**GS1 EPCglobal Tag Data Translation (TDT) 1.6**  
Ratified Standard  
October 12, 2011

Latest version: 1.6 Issue 2  
Previous versions: 1.0, 1.4

## 128 **Terminology**

129 Within this specification, the terms SHALL, SHALL NOT, SHOULD, SHOULD NOT,  
130 MAY, NEED NOT, CAN, and CANNOT are to be interpreted as specified in Annex G of  
131 the ISO/IEC Directives, Part 2, 2001, 4th edition [ISODir2]. When used in this way,  
132 these terms will always be shown in ALL CAPS; when these words appear in ordinary  
133 typeface they are intended to have their ordinary English meaning.

134 The `Courier` font is used to indicate the names of XML elements and attributes and  
135 names of variable fields within the Tag Data Translation markup.

136 All sections of this document are normative, except where explicitly noted as non-  
137 normative.

## 138 **Status of this document**

139 This document is a Ratified Standard as of September 9, 2011 and is based on the  
140 previous version which was ratified by the EPCglobal Board of Governors on June 10th,  
141 2009. It now has been updated to reflect the current functionality in TDS v1.6. The  
142 previous version of the TDT was version 1.4. We have jumped to version v1.6 for this  
143 version to imply compatibility with TDS v1.6.

144 This version of the GS1 EPC Tag Data Translation Standard is the Ratified version of the  
145 standard and has completed all process steps under the new GSMP. Please note that in  
146 Issue 2 of this document, the “Unratified Standard” watermark has been removed and this  
147 section has been updated. The technical content remains the same as the first issue of  
148 September 9<sup>th</sup>, 2011.

149 Comments on this document should be sent to the [GSMP@gs1.org](mailto:GSMP@gs1.org).

## 150 **Changes from previous versions**

151 This version of the specification supports the latest TDS version 1.6. The following  
152 changes are made to this specification:

- 153 • Added new TDT definition file for ADI-var scheme to support variable-length  
154 EPC identifier construct for Aerospace & Defence, for the unique identification of  
155 aircraft parts
- 156 • Relaxed schema restrictions for the `tagLength` and `optionKey` attributes of  
157 the `<scheme>` element in `EpcTagDataTranslation.xsd`, in order to accommodate  
158 the variable-length EPC identifiers; `tagLength` and `optionKey` are not  
159 required attributes of `<scheme>` for variable-length EPC schemes such as  
160 ADI-var.
- 161 • Provided clarification in flowcharts (Figures 9a, 9b in section 3.10.0) regarding  
162 the padding and stripping of characters or bits when converting between binary  
163 and non-binary levels; the term 'NON-BINARY' is replaced with 'TAG-  
164 ENCODING URI' since only the tag-encoding URI representation has a 1-1  
165 correspondence with the binary encoding for each of the structural elements.

166 Note that when encoding from any level other than the BINARY level, it is  
167 necessary to examine the corresponding fields within the TAG-ENCODING URI  
168 and BINARY levels in order to make use of the flowcharts in Figures 9a and 9b.  
169 (The previous version of these flowcharts did not make this sufficiently clear -  
170 and for example, a field such as itemref might be defined within the BINARY and  
171 TAG-ENCODING levels but not defined in the LEGACY level (if it cannot be  
172 unambiguously parsed from the input (an element string or GS1 Application  
173 Identifier notation) without first applying rules as defined in rule elements)

- 174 • Errata corrections to TDT definition files defined in TDT 1.4 (typically missing  
175 LEGACY\_AI levels in some schemes derived from GS1 identifier keys)
- 176 • Updates to Figures 3 through 10 and Table 2 to mention additional levels of  
177 representation introduced in TDT 1.4 and TDT 1.6.
- 178 • XML comments used throughout the XSD schema files for TDT to provide  
179 helpful annotation and explanation.

180 Previous changes introduced with TDT 1.4 relative to TDT 1.0:

- 181 • Modified tagLength attribute in schema definition to remove tagLength restriction  
182 (EpcTagDataTranslation.xsd)
- 183 • Added three new schema definition to support GSRN-96, GDTI-96 and GDTI-  
184 113
- 185 • Added example string format for GSRN and GDTI in Table 3
- 186 • Added bitPadDir attribute to the schema definition to specify padding direction  
187 for binary output. Added bitPadDir description to section 3.10 (Padding of fields)  
188 and replace existing table in this section with flow chart to provide more clarity
- 189 • Added support for additional functions to the schema definition to support  
190 arithmetic and added these functions to section 3.14 (Core Function)
- 191 • Added table entry for bitPadDir to section 4.6 (Attributes)
- 192 • Added GSRN and GDTI to section 9 (Glossary)
- 193 • Added GSRN and GDTI to the section 10 (References)

194  
195

## 196 **1 Introduction**

### 197 **1.1 Overview**

198 The Electronic Product Code (EPC) is a globally unique identifier that is designed to  
199 allow the automatic identification of objects anywhere.

200 The EPC Tag Data Standard (TDS) indicates how existing coding systems such as the  
201 GS1 (formerly EAN.UCC) family of codes (GTIN, GLN, SSCC, GRAI, GIAI, GSRN,

202 GDTI) and a small number of other identifier constructs should be embedded within the  
203 Electronic Product Code (EPC).

204 By providing a machine-readable framework for validation and translation of EPC  
205 identifiers, Tag Data Translation is designed to help to future-proof the EPC Network and  
206 in particular to reduce the pain / disruption in supporting additional EPC identifier  
207 schemes that may be introduced in the future, as the EPC Network is adopted by  
208 additional industry sectors and new applications. The EPC Tag Data Standard (TDS) also  
209 describes in terms of human-readable encoding and decoding rules for each coding  
210 scheme, how to translate between three representations of the electronic product code  
211 (EPC), namely the binary format and two formats of uniform resource identifiers (URI),  
212 one for tag-encoding and another for pure identity.

213 *The canonical representation of an EPC is the pure-identity URI representation, which is*  
214 *intended for communicating and storing EPCs in information systems, databases and*  
215 *applications, in order to insulate them from knowledge about the physical nature of the*  
216 *tag, so that although 64 bit tags may differ from 96 bit tags in the choice of literal binary*  
217 *header values and the number of bits allocated to each element or field within the EPC,*  
218 *the pure-identity URI format does not require the information systems to know about*  
219 *these details; the pure-identity URI can be just a pure identifier.*

220 *The binary format is used to store the EPC identifier in the EPC/UII memory of the RFID*  
221 *tag. The binary format consists of a header (which indicates the coding scheme and*  
222 *version - usually the first 8 bits, although a 2-bit header was defined for SGTIN-64), a*  
223 *fast filter value (which can be used for distinguishing between different packaging*  
224 *levels), as well as fields indicating the company responsible for the object, the object*  
225 *class and a unique serial number.*

226 *The tag-encoding URI provides a 1-1 mapping with the binary number recorded in the*  
227 *physical tag and as such indicates the bit-length of the tag (for fixed-length EPCs) and*  
228 *usually also includes an additional field (usually 3 bits) which is reserved for fast*  
229 *filtering purposes, e.g. to distinguish between various packaging levels for trade items.*  
230 *The tag-encoding URI is therefore intended for low-level applications which need to*  
231 *write EPCs to tags or physically sort items based on packaging level.*

232 *The pure-identity URI format isolates the application software from details of the bit-*  
233 *length of the tags or any fast filtering values, so that tags of different bit-lengths which*  
234 *code for the same unique object will result in an identical pure-identity URI, even though*  
235 *their tag-encoding URIs and binary representations may differ. This means that when a*  
236 *manufacturer switches from using 64-bit tags to 96-bit tags or longer for tagging a*  
237 *particular product, the pure-identity URI representation of the EPC will appear the same*  
238 *(except for different serial numbers for different instances of the product).*

239 *Section E.3 of Appendix E of Tag Data Standard v1.6 provides examples of the pure-*  
240 *identity URI, tag-encoding URI and binary encoding for all current EPC schemes.*

241 The EPC Tag Data Translation (TDT) standard is concerned with a machine-readable  
242 version of the EPC Tag Data Standard rules for formatting and translation of EPC  
243 identifiers. The machine-readable version can be readily used for validating EPC formats  
244 as well as translating between the different levels of representation in a consistent way.

245 This standard describes how to interpret the machine-readable version. It contains details  
246 of the structure and elements of the machine-readable markup files and provides guidance  
247 on how it might be used in automatic translation or validation software, whether  
248 standalone or embedded in other systems.

## 249 **1.2 Tag Data Translation Charter**

250 The three objectives in the original charter of the Tag Data Translation working group  
251 were:

- 252 • To develop the necessary specifications to express the current TDS encoding and  
253 decoding rules in an unambiguous machine-readable format; this will allow any  
254 component in the EPC Network technology stack to automatically translate between  
255 the binary and tag-encoding URI and pure-identity URI formats of the EPC as  
256 appropriate. The motivation is to allow components flexibility in how they receive or  
257 transmit EPCs, to reduce potential 'impedance mismatches' at interfaces in the EPC  
258 Network technology stack. Reference implementations of software that demonstrate  
259 these capabilities will also be developed.
- 260 • To provide documentation of the TDS encodings in such a way that the current prose  
261 based documentation can be supplemented by the more structured machine-readable  
262 formats.
- 263 • To ensure that automated tag data translation processes can continue to function and  
264 also handle additional numbering schemes, which might be embedded within the EPC  
265 in the future. By aiming for a future-proof mechanism which allows for smooth  
266 upgrading to handle longer tags (e.g. 256 bits) and the incorporation of additional  
267 encoding/decoding rules for other coding systems, we expect to substantially reduce  
268 the marginal cost of redeveloping and upgrading software as the industry domains  
269 covered by the EPC expand in the future. We envisage that data which specifies the  
270 new rules for additional coding schemes will be readily available for download in  
271 much the same way as current anti-virus software can keep itself up to date by  
272 periodically downloading new definition files from an authoritative source.

273

## 274 **1.3 Tag Data Translation Concept**

275 The Tag Data Translation process translates one representation of EPC into another  
276 representation, within a particular coding scheme. For example, it could translate from  
277 the binary format for a GTIN on a 96-bit tag to a pure-identity URI representation of the  
278 same identifier, although it could not translate a SSCC into a SGTIN or vice versa.

279 The Tag Data Translation concept is illustrated in Figure 1.

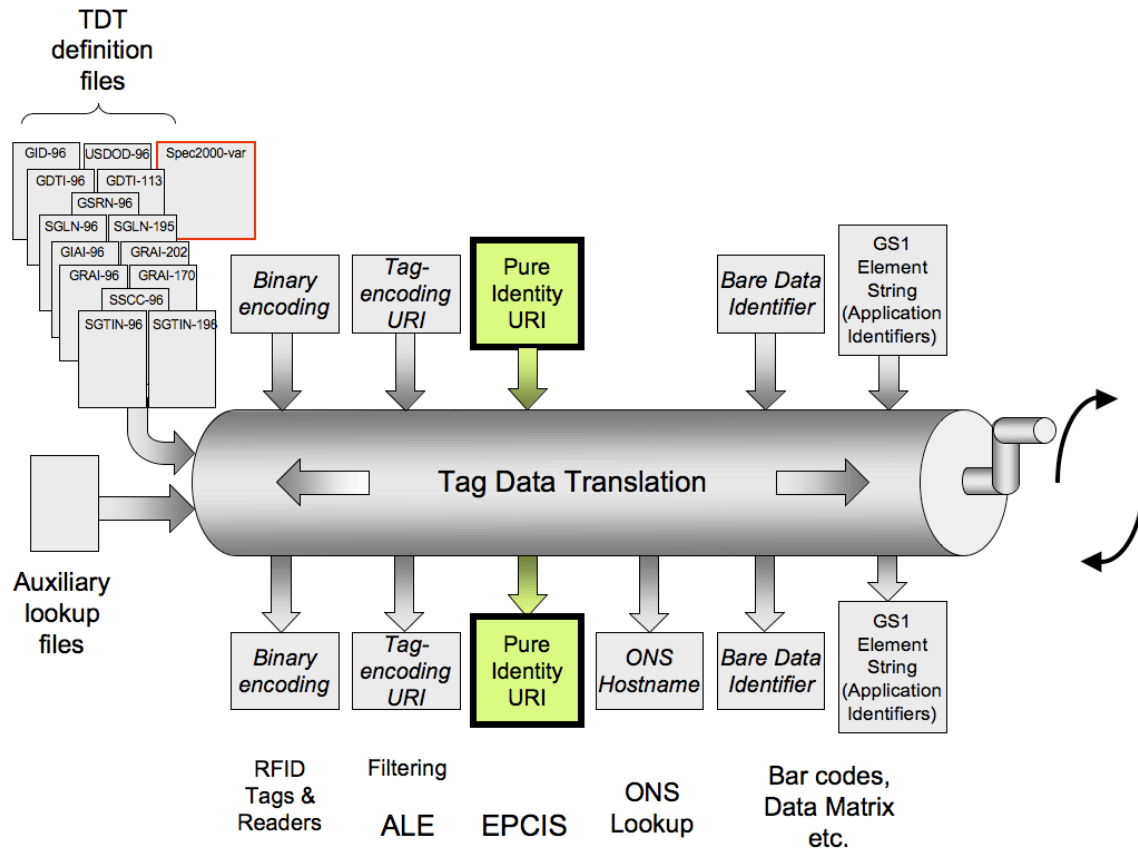

Figure 1 - Tag Data Translation - Concept

280

281

282

283 Tag Data Translation capabilities may be implemented at any level of the EPC Network  
 284 stack, from readers, through filtering middleware, as a pre-resolver to the Object Name  
 285 Service (ONS), as well as by applications and networked databases complying with the  
 286 EPCIS interface. Tag Data Translation converts between different levels of representation  
 287 of the EPC and may make use of external tables, such as the GS1 Company Prefix Index  
 288 lookup table for 64-bit tags. It is envisaged that Tag Data Translation software will be  
 289 able to keep itself up-to-date by periodically checking for and downloading TDT markup  
 290 files, although a continuous network connection should not be required for performing  
 291 translations or validations, since the TDT markup files and any auxiliary tables can be  
 292 cached between periodic checks; in this way a generic translation mechanism can be  
 293 extensible to further coding schemes or variations for longer tag lengths, which may be  
 294 introduced in the future.

295

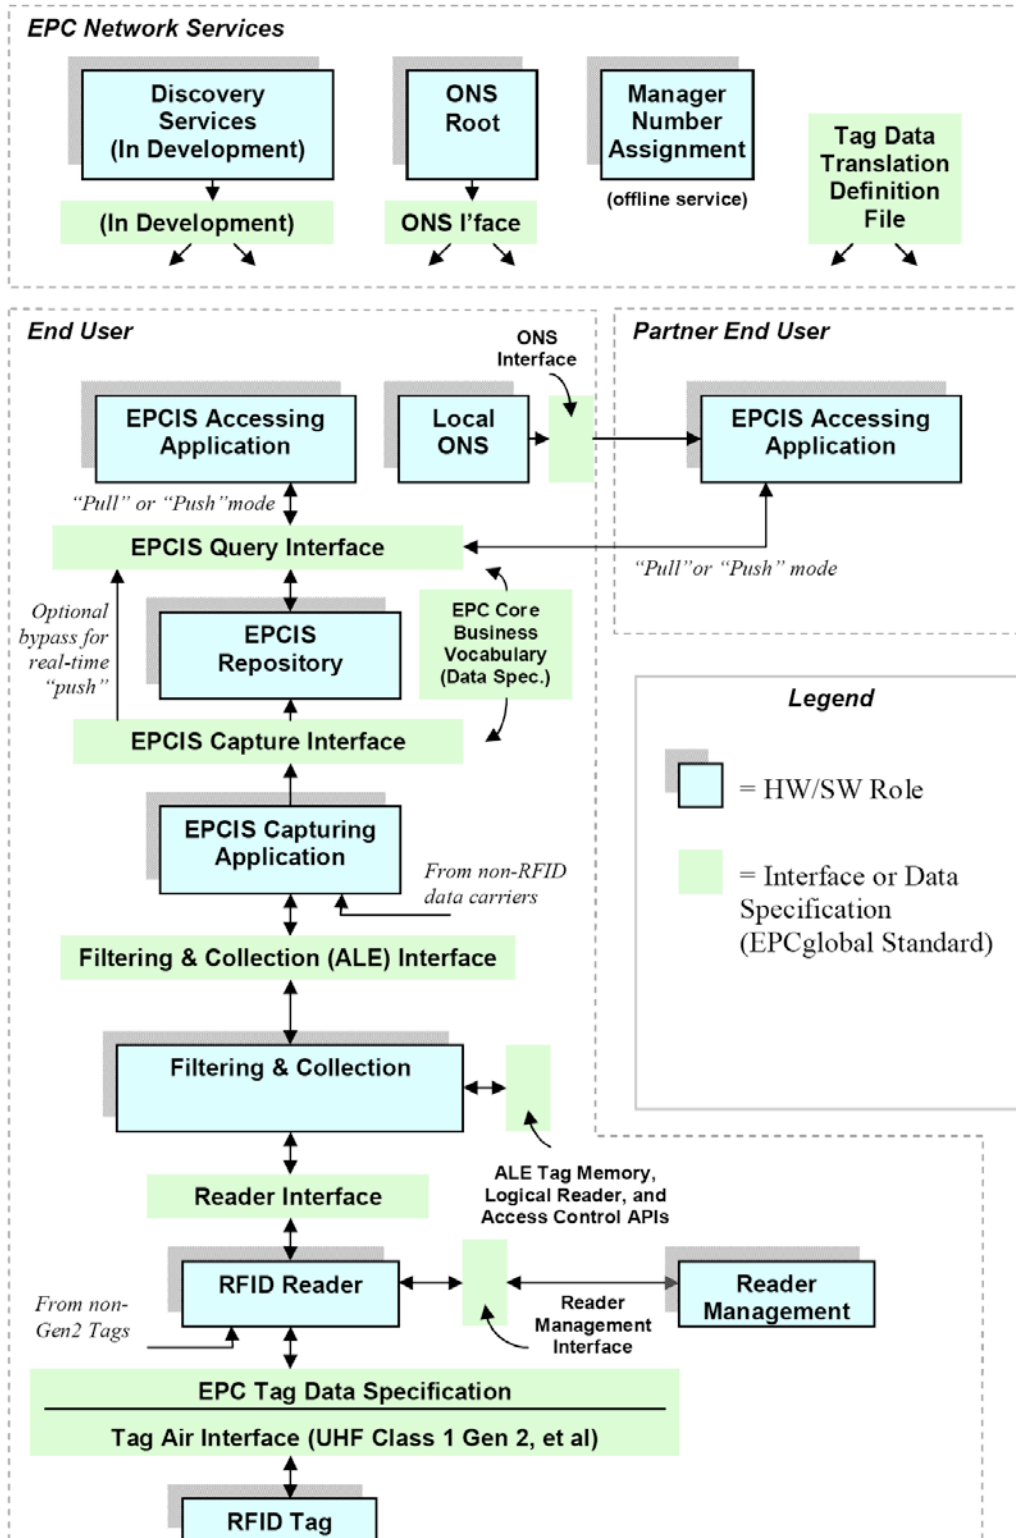

296 *Although the TDT markup files are made available in XML format, this does not impose a*  
 297 *requirement for all levels of the EPC Network technology stack to implement XML*  
 298 *parsers. Indeed, TDT functionality may be included within derived products and services*  
 299 *offered by solution providers and the existence of additional or updated TDT definition*  
 300 *files may be reflected within software/firmware updates released by those providers.*

301 *Authoritative TDT definition files and schema are made freely available for anyone to*  
302 *download from the standards section of the GSI EPCglobal website. For example, the*  
303 *manufacturer of an RFID reader may regularly check for and obtain the current TDT*  
304 *markup files, then use data binding software to convert these into hierarchical software*  
305 *data objects, which could be saved more compactly as serialized objects accessible from*  
306 *the particular programming language in which their reader software/firmware is written.*  
307 *The reader manufacturer could make these serialized objects available for download to*  
308 *owners of their products – or bundle them with firmware updates, thus eliminating the*  
309 *need for either embedded or real-time parsing of the TDT markup files in their original*  
310 *XML format at the reader level.*

311

## 312 **1.4 Role within the EPC Network Architecture**

313 In the EPC Network Architecture [EPC Network Architecture Framework document] as  
314 depicted in Figure 2 below, the green bars denote interfaces governed by EPCglobal  
315 standards, while the blue boxes denote roles played by hardware and/or software  
316 components of the system.

317  
318  
319

Figure 2 - EPC Network Architecture diagram

320 Table 1 describes the key elements of the EPC Network and the potential usages for the  
 321 Tag Data Translation process for encoding and decoding Tag Data Standard.

<b>EPC Network Standards</b>	<b>Description</b>	<b>TDT Role</b>	<b>Potential TDT Usage</b>
Lower Level Reader Protocol (LLRP)	Defines the control and delivery of raw tag reads from Readers to F&C Middleware	Yes	Conversion upon 'impedance mismatch' of EPC representation
Application Level Events (ALE) Filtering & Collection	API for software that filters and collects raw tag reads, over time intervals delimited by event cycles as defined by applications such as the EPCIS Capturing Application	Yes	Conversion of other EPC representations into URI format for reports  Assistance with converting declarative URI patterns into combinations of bit-mask
EPCIS Capturing Application	Software that supervises the operation of the lower EPC network elements and coordinates with enterprise level business events	Yes	Conversion upon 'impedance mismatch' of EPC representation
ONS	ONS is a network service layered over the existing Domain Name System that is used to lookup authoritative pointers to EPCIS-enabled Repositories and other EPC-related information services, given an EPC Manager Number or full Electronic Product Code	No	TDT provides an output-only format which is the hostname for DNS type 35 lookup, in order to perform an ONS query
EPCIS Service Repository	Networked database or information system providing query/update access to EPC-related data	No	In underlying databases, EPCs might be stored in other formats (e.g. GTIN+serial, separately – or hexadecimal). TDT can convert these to URI formats
EPCIS Enabled Application	Application software responsible for carrying out overall enterprise business processes, such as warehouse management, shipping and receiving	No	Conversion upon 'impedance mismatch' of EPC representation
Trading Partner Application	Trading Partner software that performs the role of an EPCIS Accessing Application.	No	Conversion upon 'impedance mismatch' of EPC representation

322

323

*Table 1 – Potential role for Tag Data Translation throughout the EPC Network*

324

325 The majority of the EPC Network components require the ability to consistently translate  
326 between binary data on tags and URI formats for information systems. However, it  
327 should be noted that levels of the stack above the Low Level Reader Protocol interface  
328 should normally be using the URI representation rather than the binary representation.  
329 This also enforces a need for a standard translation mechanism across the entire EPC  
330 network so that the translation process and resulting data is consistent and valid.

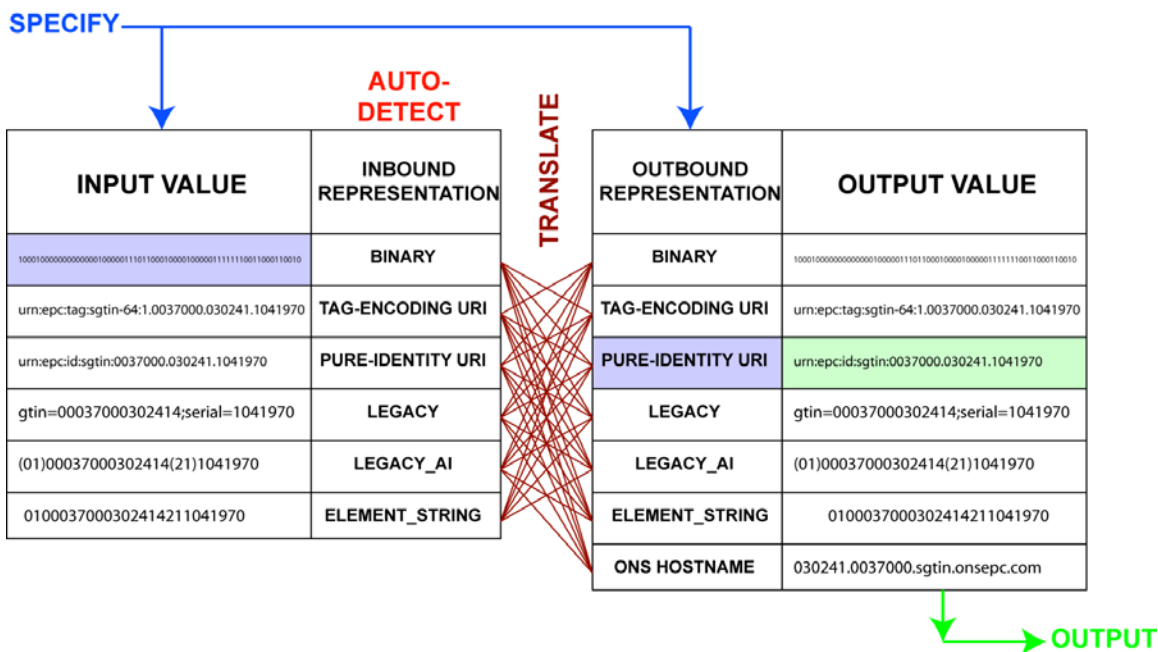

331

### 332 1.5 Tag Data Translation Process

333 The fundamental concept of Tag Data Translation is to automatically convert one  
334 representation of an EPC (whether binary, tag-encoding URI, pure-identity URI) or a  
335 serialized element string – and convert it into another representation as required.

336 This is illustrated in Figure 3

337

338

339 Figure 3 - Tag Data Translation process with examples of different representations.

340

341 The Tag Data Translation process takes an input value in a particular representation  
342 (binary / tag-encoding URI / pure-identity URI). We refer to the representation in which  
343 the input value is expressed as the inbound representation. In the conversion process, the  
344 desired outbound representation is also specified by the client requesting the translation.  
345 The Tag Data Translation process then returns an output value that is the input value after  
346 translation from the inbound representation to the outbound representation.

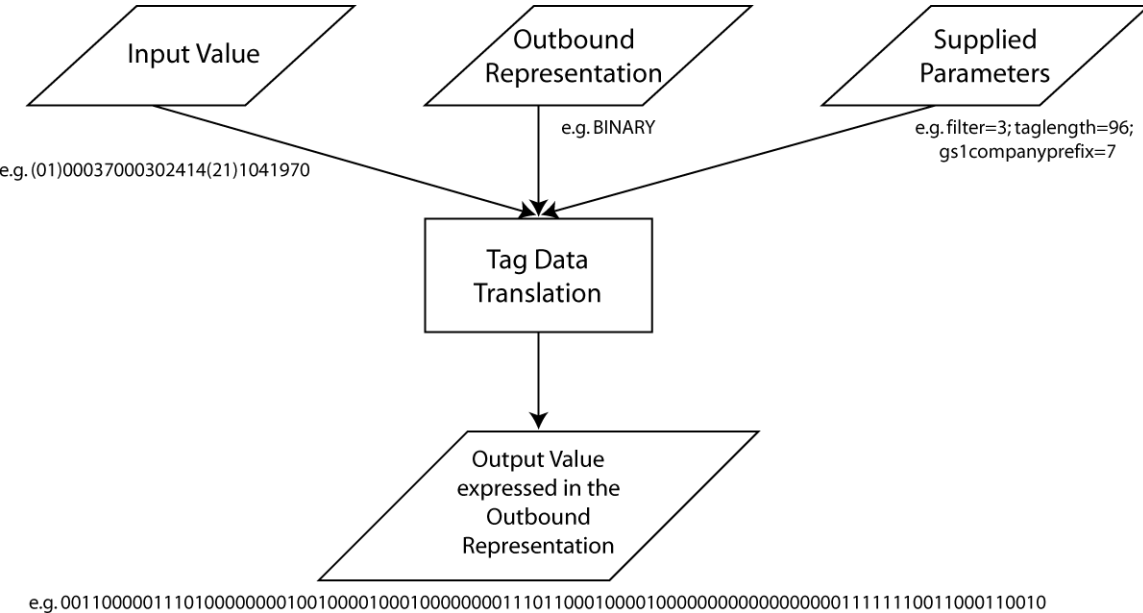

347

348 In practice, some representations contain more information than others. For example, the  
 349 binary and tag-encoding URI representations also contain information about the number  
 350 of bits used to store the EPC identifier on a physical RFID tag. They also contain  
 351 information about a fast filter value, which can be used to discriminate between different  
 352 packaging levels for trade items.

353 The serialized element strings contain the essential information (company, [object class, ]  
 354 serial number) for an EPC – but often they do not clearly indicate the boundary between  
 355 the company identifier and the object class identifier – so additional information needs to  
 356 be supplied, such as the length of the company identifier, from which the boundary can  
 357 be determined..

358 This means that as well as providing an input value and a required outbound  
 359 representation, there are cases where additional parameters need to be supplied. This is  
 360 illustrated in Figure 4

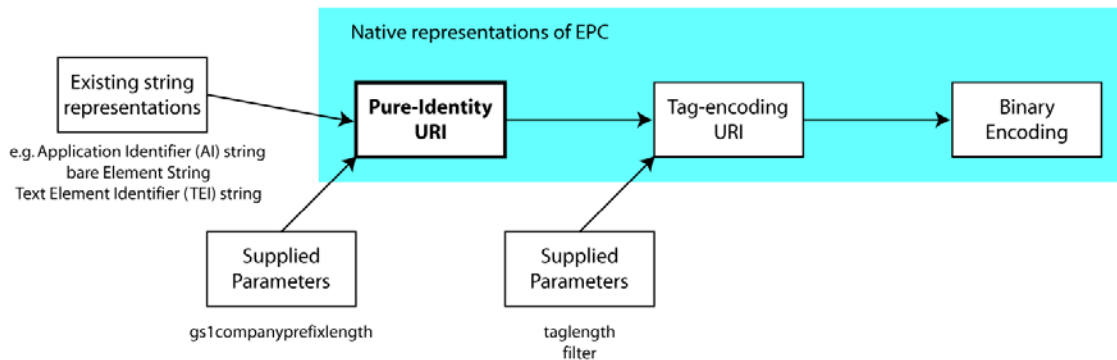

361

362  
 363 *Figure 4 - Flowchart showing input and output parameters to a Tag Data Translation*  
 364 *process.*  
 365

366 In the context of Tag Data Translation, we refer to encoding as any conversion of the  
 367 format in the direction of the binary representation, whereas decoding is any conversion  
 368 away from the binary representation. This is illustrated in Figure 5.

## ENCODING

## DECODING

369

370

371

372

*Figure 5 - Encoding and Decoding between different representations of an EPC. Note that when encoding, additional parameters need to be supplied.*

373

374

375

376

377

378

379

380

381

382

383

384

385

386

387

388

389

390

In Figure 5 above, there are actually two distinct groups of supplied parameters – those such as `gs1companyprefixlength` which are required for parsing the input value when it is an element string or expressed in GS1 Application Identifier representation – and others such as `filter` and `tagLength`, which are required to format the output for certain levels of representation, such as binary or tag-encoding URI. In order to assist Tag Data Translation software in checking that all the required information has been supplied to perform a translation, the `<level>` elements of the Tag Data Translation markup files may contain the attribute `requiredParsingParameters` to indicate which parameters are required for parsing input values from that level and `requiredFormattingParameters` to indicate which parameters are required for formatting the output at that outbound representation level. Further details on these attributes appear in Chapter 4, which describes the TDT markup files. Note that `tagLength` is not a required formatting parameter nor a required parsing parameter for levels other than binary or tag-encoding URI and this means that there can be situations where more than one TDT definition file has a pattern matching the input (e.g. if converting an SGTIN with an all-numeric serial number from pure-identity URI representation to any level of representation except binary or tag-encoding URI). In such situations, it does not matter which of the matching definition files is selected.

391

392

393

394

A list of GS1 Company Prefixes of EPCglobal subscribers (without attributions) is available at the website <http://www.onsepc.com> in either XML or plain text format. From this list, it is possible to identify a suitable GS1 Company Prefix and therefore to determine its length in characters. This can then be passed as the value of the parameter

395 gs1companyprefixlength, which should be supplied when translating from GS1  
396 identifier keys to binary, tag-encoding URI or pure-identity URI representations. For the  
397 appropriate choice of filter value to use with a particular identifier scheme, please refer  
398 to the filter tables defined in EPCglobal Tag Data Standard. The tagLength parameter is  
399 used to help an implementation of Tag Data Translation to select the appropriate TDT  
400 definition file among EPC schemes that correspond to the same identifier but differ in  
401 length, e.g. to choose between GRAI-64, GRAI-96, GRAI-170 depending on whether  
402 the value of tagLength is set to 64, 96 or 170. For the value of the tagLength parameter,  
403 please also consider the available size (in bits) for the EPC identifier memory in the  
404 RFID tag (e.g. 96 bits) - and whether this is sufficient. [Non-normative example: For  
405 example, a GRAI-170 supports alphanumeric serial codes but cannot be encoded  
406 within a 96-bit tag.]  
407

408 A desirable feature of a Tag Data Translation process is the ability to automatically detect  
409 both the coding scheme and the inbound representation of the input value. This is  
410 particularly important when multiple tags are being read – when potentially several  
411 different coding schemes could all be used together and read simultaneously.

412 *For example, a shipment arriving on a pallet may consist of a number of cases tagged*  
413 *with SGTIN identifiers and a returnable pallet identified by a GRAI identifier but also*  
414 *carrying an SSCC identifier to identify the shipment as a whole. If a portal reader at a*  
415 *dock door simply returns a number of binary EPCs, it is helpful to have translation*  
416 *software which can automatically detect which binary values correspond to which coding*  
417 *scheme, rather than requiring that the coding scheme and inbound representation are*  
418 *specified in addition to the input value.*

## 419 **1.6 Expressing different representations of EPC**

### 420 **Patterns (Regular Expressions)**

421 Given an input value, regular expression patterns may be used to match and extract  
422 groups of characters, digits or bits from the input value, in order that their values may  
423 later be used for constructing the output value in the desired outbound representation,  
424 after suitable manipulation, such as binary – decimal conversion, padding etc. We refer  
425 to these variable parts as 'fields'. Examples of fields include the GS1 Company Prefix  
426 (which usually identifies the manufacturer), the Serial Number, Fast Filter value etc.

### 427 **Grammar (Augmented Backus-Naur Form [ABNF])**

428 An Augmented Backus-Naur Form (ABNF) grammar may be used to express how the  
429 output is reassembled from a sequence of literal values such as URN prefixes and fixed  
430 binary headers with the variable components, i.e. the values of the various fields. For the  
431 grammar attributes of the TDT markup files, in accordance with the ABNF grammar  
432 conventions, fixed literal strings SHALL be single-quoted, whereas unquoted strings  
433 SHALL indicate that the value of the field named by the unquoted string SHOULD BE  
434 inserted in place of the unquoted string.

## 435 **Rules for obtaining additional fields**

436 However, not all fields that are required for formatting the output value are obtained  
437 directly from pattern-matching of the inbound representation. Sometimes additional  
438 fields are required to be known. For example, when translating a SGTIN-64 from binary  
439 to element strings, it will be possible to extract a GS1 Company Prefix Index, Item  
440 Reference and Serial Number from pattern-matching on the binary input – but the  
441 outbound representation needs other fields such as GS1 Company Prefix, Check Digit,  
442 Indicator Digit, which SHOULD be derived from the fields extracted from the inbound  
443 representation. For this reason, the TDT markup files also include sequences of rules,  
444 mainly within the element strings and binary levels. The rules express how such  
445 additional fields may be calculated or obtained via functions operating on fields whose  
446 values are already known.

447 Furthermore, there are some fields that cannot even be derived from fields whose values  
448 are already known and which SHALL therefore be specified independently as supplied  
449 parameters. For example, when translating a GTIN value together with a serial number  
450 into the binary representation, it is necessary to specify independently which length of tag  
451 to use (e.g. 64 bit or 96 bit) and also the fast filter value to be used. Such supplied  
452 parameters would be specified in addition to specifying the input value and the desired  
453 outbound representation. As illustrated in Figure 5, additional parameters SHOULD be  
454 supplied together with the input value when performing encoding. For decoding, it is  
455 generally not necessary to supply any additional parameters.

456

## 457 **1.7 Translation Process Steps**

458 There are five fundamental steps to a translation:

- 459 1. Use of the prefix matches and regular expression patterns to automatically detect  
460 the inbound representation and coding scheme of the supplied input value
- 461 2. Using the regular expression pattern to extract values of fields from the input  
462 value
- 463 3. Manipulation, (string manipulation, binary – decimal/alphanumeric conversion,  
464 padding etc.) of values of those fields in order to translate from the inbound  
465 representation to the outbound representation
- 466 4. Using the rules to calculate any additional fields required for the output
- 467 5. Using the ABNF grammar to format the required fields in the appropriate output  
468 representation

469

470 Note that the `prefixMatch` attribute in the TDT markup files is provided to allow  
471 optimization of software implementations to perform auto-detection of input  
472 representation more efficiently. Where multiple `option` elements are specified within a  
473 particular `level` element, each will generally have a `pattern` attribute with a subtly  
474 different regular expression as its value. The `prefixMatch` attribute of the enclosing

475 level element expresses an initial prefix of these patterns which is common to all of the  
476 nested options. Optimized software need not test each nested option for a pattern match  
477 if the value of the `prefixMatch` attribute fails to match at the start of the input value.  
478 Only for those levels where the `prefixMatch` attribute matches at the start of the string  
479 should the patterns of the nested options be considered for matching.

480 Note that in the TDT markup files, the `prefixMatch` attribute SHALL be expressed as  
481 a substring to match at the beginning of the input value. The `prefixMatch` attribute  
482 SHOULD NOT be expressed in the TDT markup files as a regular expression value,  
483 since a simple string match should suffice. Software implementations MAY convert the  
484 `prefixMatch` attribute string value into a regular expression, if preferred, for example by  
485 prefixing with a leading caret [`^`] symbol (to require a match at the start of the string)  
486 and by escaping certain characters as required, e.g. escaping the dot character as `\.` or  
487 `\\.`.

488

## 489 **2 Tag Data Standard**

### 490 **2.1 Overview**

491 In the EPC Tag Data Standard, the canonical representation of an Electronic Product  
492 Code (EPC) is as a pure-identity URI. This is to be used when an EPC is communicated  
493 within software applications and information systems, EPCIS and when information  
494 about EPCs is exchanged between organizations, since these systems should not be  
495 concerned with the nature of the physical tag in which the EPC was encoded - or indeed  
496 whether the EPC was encoded within an RFID tag, a barcode or DataMatrix symbol.  
497 When an EPC is encoded within the EPC/UII memory bank of an RFID tag, a binary  
498 encoding is used. This binary encoding includes additional information such as an  
499 indication of the length of the EPC (for fixed-length EPCs) and a filter value. A tag-  
500 encoding URI format is also defined, which provides a faithful representation of all of the  
501 information contained within the binary encoding of an EPC. We therefore have to  
502 concern ourselves with three representations of the Electronic Product Code, namely  
503 binary encoding, tag-encoding URI and pure-identity URI.

504 Furthermore, the EPC Tag Data Standard specification (v1.6) describes how a number of  
505 the GS1 (formerly EAN.UCC) coding schemes (GTIN, SSCC, GLN, GRAI, GIAI,  
506 GSRN and GDTI) should be embedded within the EPC for 64-bit, 96-bit and larger tags  
507 for GTIN, GRAI, GIAI and GDTI to support alpha-numeric serial number. The  
508 Electronic Product Code (EPC) is intended to enable unique identification of any object  
509 anywhere automatically. Many of the existing GS1 identifier keys (SSCC, GRAI and  
510 GIAI) are already fully serialised. Others, such as the GTIN represent a product class  
511 rather than an individual fully serialized object. For use with the EPC, some GS1  
512 identifiers (e.g. GTIN, GLN) may be accompanied with an additional serial number and  
513 referred to as SGTIN, SGLN.

514 Although technically the serialised GS1 codes are not themselves a representation of the  
515 EPC, they can be encoded into- and decoded from the three representations of EPC, as

516 described in the EPC Tag Data Standard specification – so for this reason we consider  
517 various representation levels for a EPC Tag Data Translation process as illustrated in  
518 Table 2.

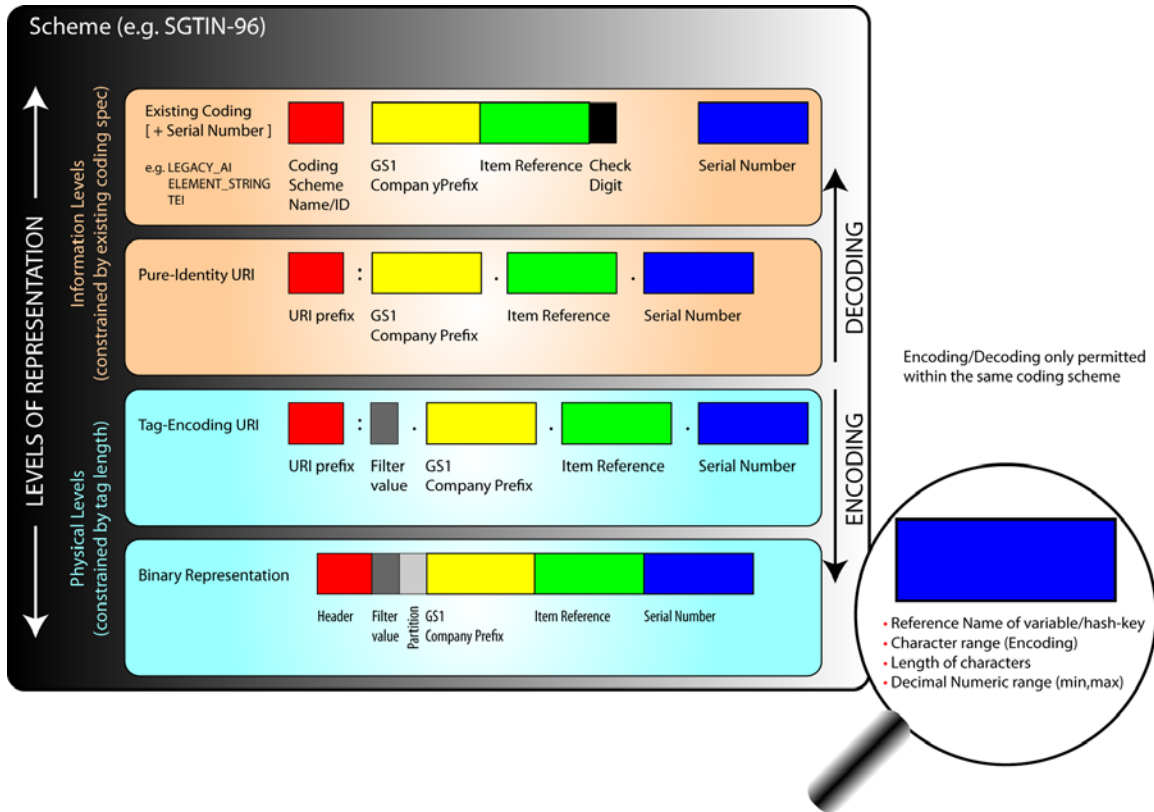

519

EN C O D E ↓	7	Hostname for DNS type 35 query in order to perform an ONS lookup	Output-only format	↑ D E C O D E
	6	Text Element Identifier string (where appropriate, e.g. ADI)	Constrained by specifications of existing coding schemes Does not express tag length, filter value	
	5	Application Identifier string or bare Element String		
	4	Serialized human-readable representation (SGTIN,SSCC,SGLN,GRAI,GIAI)		
	3	Pure-identity URI format of EPC		
	2	Tag-encoding URI format of EPC	Constrained by number of bits available in physical tag. Expresses tag length, filter value	
	1	Binary representation of EPC		

521 *Table 2 - Levels of representation involved in the Translation Process*

522

523 As Table 2 indicates, the various 'levels' involved in the translation process are not  
 524 completely equivalent. There is a one-to-one mapping between the pair of levels  
 525 numbered 1 and 2 (binary and tag-encoding URI) and between the pair of levels  
 526 numbered 3 and 4 (pure-identity URI and serialized element string). The levels 3 and 4  
 527 lack the information present in levels 1 and 2 about tag length and fast filtering value.  
 528 This is illustrated in more detail in Figure 6 below. Levels 5 and 6 shown in Table 2 are  
 529 simply additional string representations of the main elements contained within the Pure-  
 530 identity URI representation, to support ease of integration with identifiers encoded within  
 531 linear barcodes or 2-dimensional barcodes. Note that for convenience, TDT 1.6 provides  
 532 a further 'level' of representation, corresponding to the hostname for which a DNS Type  
 533 35 (NAPTR) query should be performed in order to effect an ONS lookup. This is not  
 534 strictly an equivalent level of representation of EPC, since ONS v1.0 does not currently  
 535 provide serial-level pointers for all coding schemes. It is therefore an output-only format  
 536 and not a valid input format for encoding purposes. For this reason, only an ABNF  
 537 grammar is defined for formatting the output in the ONS hostname representation – and  
 538 no regular expression is defined for parsing the ONS hostname representation as input.  
 539 i.e. in the TDT markup files, the `pattern` attribute SHALL always be absent from the  
 540 `level` element representing the ONS hostname format. This SHALL indicate to  
 541 translation software that any auto-detection of the inbound representation SHALL NOT  
 542 consider the ONS hostname representation as a valid input.

543

544

545 *Figure 6 - Comparison of the data elements present in each level of each scheme.*

546 *Note that the level marked as 'Existing Coding' in Figure 6 corresponds to levels 4-6 of*

547 *Table 2.*

## 548 2.2 Many Schemes, Multiple Levels within each scheme and

### 549 multiple options within each level

550 We refer to each EPC coding system (SGTIN, SSCC, SGLN, GRAI, GIAI, GSRN,  
 551 GDTI, USDOD, ADI and GID) as a scheme. The GS1 EPC Tag Data Standard defines  
 552 the structure and encoding/decoding rules for each EPC scheme. Note that Tag Data  
 553 Translation provides separate definition files for each EPC scheme and for each permitted  
 554 length of the binary encoding for fixed-length EPC schemes. e.g. TDT provides separate  
 555 definition files for SGTIN-64, SGTIN-96, SGTIN-198. Within each scheme, there are  
 556 various levels of representation (binary, tag-encoding URI, pure-identity URI as well as  
 557 string representations and ONS hostname).

558 Furthermore, the GS1 identifier keys use a GS1 Company Prefix of variable length,  
 559 between 6 and 12 decimal digits. The TDS specification takes two different approaches  
 560 to handling this in the 64-bit and 96-bit schemes. For the 64-bit schemes, an integer-  
 561 based GS1 Company Prefix Index is encoded into the binary representation, in order to  
 562 accommodate a larger range of numbers for the Item Reference and Serial Number  
 563 partitions. The GS1 Company Prefix is obtained from the encoded Company Prefix  
 564 Index by lookup in a table and it is always the GS1 Company Prefix that appears in the

565 URI formats. For the 96-bit schemes, a 3-bit field (the partition value) following the fast  
566 filter value within the binary representation is used to indicate the length of the GS1  
567 Company Prefix, in the range 6-12 digits, denoted by binary partition values 000 – 110.  
568 The bit-length partitions allocated to the GS1 Company Prefix and Item Reference fields  
569 varies accordingly as described in the EPC Tag Data Standard.

570 One option would be to use a separate lookup table for the partition values as described in  
571 the TDS specification. However, since the correspondence between the partition value  
572 and the length of the GS1 Company Prefix is common to all the GS1 schemes and the  
573 partition table is static in nature, we propose a more pragmatic approach and instead  
574 embed 7 variants ('Options') of the coding structure within each level, with the  
575 appropriate Option being selected either by matching a hard-coded partition value from  
576 the inbound data (where this is supplied in binary representation) – or from the length of  
577 the GS1 Company Prefix (which SHALL be supplied independently if encoding from the  
578 GS1 identifier key). This approach also allows the TDT markup files to specify the  
579 length and minimum and maximum values for each field, which will often vary,  
580 depending on which Option was selected – i.e. depending on the length of the GS1  
581 Company Prefix used.

582 *In TDT 1.6, different Option elements are also used within the TDT definition file for the*  
583 *variable-length EPC ADI-var to support the permitted alternative variations within that*  
584 *EPC regarding how the unique identifier is constructed.*

585 For each option, the representation of the EPC is expressed as both a regular expression  
586 pattern to match the inbound representation against, and as an Augmented Backus-Naur  
587 Form (ABNF) grammar for formatting the outbound representation.

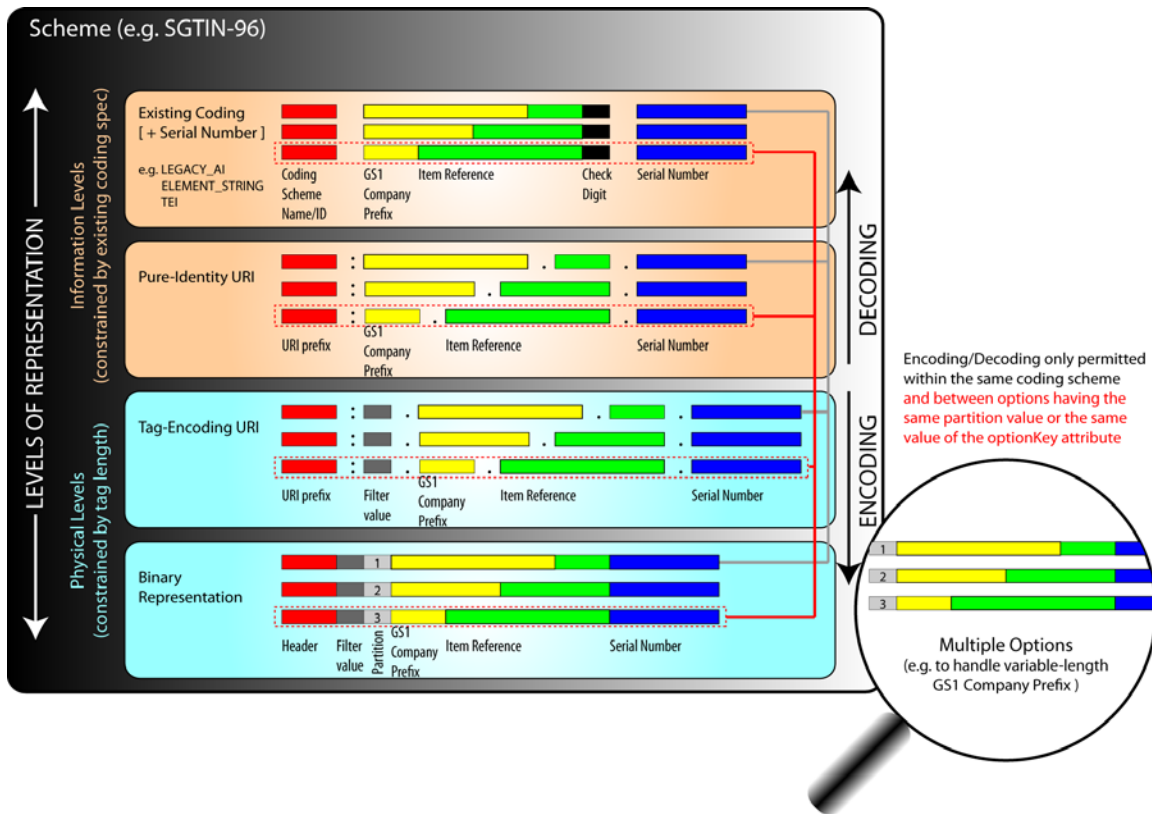

588 The regular expression patterns and ABNF grammar are therefore subtly different for  
589 each of the options within a particular level – usually in the literal values of the bits for  
590 the partition value and lengths of digits or bits for each of the subsequent partitions  
591 (where delimiters such as a period '.' separate these partitions) – or in the case of the  
592 element strings and binary representation, the way in which groups of digits or bits are  
593 grouped within the regular expression pattern. This approach facilitates the automatic  
594 detection of the boundary between GS1 company prefix and item reference simply by  
595 regular expression pattern matching, although care should be taken to ensure that only  
596 one option has a pattern that matches any valid input for that EPC scheme. Negative  
597 lookahead constructs within regular expressions can be helpful for ensuring this.

598 Within each option, the various fields matched using the regular expression are specified,  
599 together with any constraints which may apply to them (e.g. maximum and minimum  
600 values), as well as information about how they should be properly formatted in both  
601 binary and non-binary (i.e. information about the number of characters or bits, when a  
602 certain length is required, as well as information about any padding conventions which  
603 are to be used (e.g. left-pad with '0' to reach the required length of a particular field). The  
604 concept of multiple options within each level of each scheme is illustrated in Figure 7.

605

606

607

608 *Figure 7 - Depiction of multiple options within each level to handle variable-length GS1*  
 609 *Company Prefixes. Note that the level marked as 'Existing Coding' within Figure 7*  
 610 *corresponds to levels 4-6 of Table 2.*

### 611 3 TDT Markup and Logical Process

612 The key element of the above architecture is the collection of TDT markup files, which  
 613 enables encoding and decoding between various levels of representation for each  
 614 particular coding scheme. This generic design requires open and highly flexible  
 615 representation of rules for translation software to encode/decode based on the input value.  
 616 The TDT markup language is a machine-readable XML format expressing the  
 617 encoding/decoding and validation rules for various identifiers / coding schemes defined  
 618 in the TDS specification. The TDT markup SHALL be created and maintained by  
 619 EPCglobal for all the identities defined by the EPC Tag Data Standard specification.

620 This chapter provides a descriptive explanation of how to interpret the TDT Markup files  
 621 in the context of a Tag Data Translation process. Chapter 4 provides a formal  
 622 explanation of the elements and attributes of the TDT markup files.

#### 623 3.1 TDT Artifacts

624 Individual TDT definition files are provided for each coding scheme (i.e. separate files  
 625 for SGTIN-64, SGTIN-96, SSCC-64, SSCC-96, GID-96, etc.) and are made freely  
 626 available for public download from the EPCglobal web page for the TDT standard

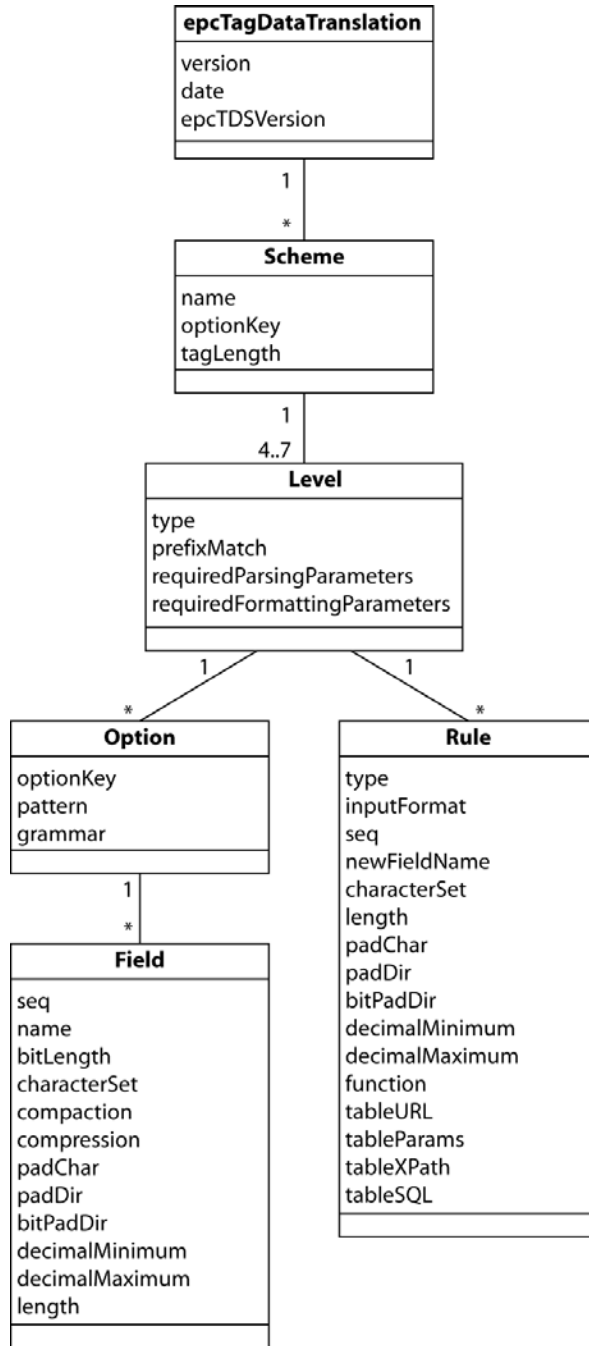

627 [ <http://www.gs1.org/gsm/kc/epcglobal/tdt> ]. Also available are the corresponding XSD  
628 schema files.

629 Version control is achieved within each artifact file via version numbers and timestamps  
630 of updates.

### 631 **3.2 TDT Markup**

632 The key elements of the TDT markup are defined in the XSD schema files and shown in  
633 Figure 8.

634

635 *Figure 8 - Tag Data Translation Markup Language schema as a UML class diagram*

636

The TDT specification uses regular expression patterns and Augmented Backus-Naur Form (ABNF) grammar expressions to express the structure of the EPC in various levels of representation.

The regular expression patterns are primarily intended to be used to match the input value and extract values of particular fields via groups of bits, digits and characters which are indicated within the conventional round bracket parentheses used in regular expressions.

The regular expression patterns provided in the TDT markup files SHALL be written according to the Perl-Compliant Regular Expressions, with support for zero-length negative lookahead.

*It is not sufficient to use the XSD regexp type as documented at <http://www.w3.org/TR/xmlschema-2/> because it is sometimes useful to be able to use a negative lookahead '?'!' construct within the regular expressions. The implementations of regular expressions in Perl, Java, C#, .NET all allow for negative lookahead. Note that the TDT definition file for ADI-var makes use of the negative lookahead construct in the patterns at the BINARY level in order to make the patterns more restrictive and avoid the situation where a valid binary string might match more than one option.*

The ABNF grammar form allows us to express the outbound string as a concatenation of fixed literal values and fields whose values are variables determined during the translation process. In the ABNF grammar, the fixed literal values are enclosed in single quotes, while the names of the variable elements are unquoted, indicating that their values should be substituted for the names at this position in the grammar. All elements of the grammar are separated by space characters. We use the Augmented Backus-Naur Form (ABNF) for the grammar rather than simple Backus-Naur Form (BNF) in order to improve readability because the latter requires the use of angle brackets around the names of variable fields, which would need to be escaped to &lt; and &gt; respectively for use in an XML document.

The child 'Field' elements within each option allow the constraints and formatting conventions for each individual field to be specified unambiguously, for the purposes of error-checking and validation of EPCs.

The use of regular expression patterns, ABNF grammar and separate nested (child) field elements with attributes for each of the fields allows for the constraints (minimum, maximum values, character set, required field length etc.) to be specified independently for each field, providing flexibility in the URI formats, so that for example an alphanumeric serial number field could co-exist alongside a decimal GS1 Company Prefix field, as would be required to support the full range of possible GRAI codes for a future tag with a larger number of bits devoted to the EPC identifier.

### 677 **3.4 Determination of the inbound representation**

678 A desirable feature of any Tag Data Translation software is the ability to automatically  
679 detect the format of the inbound string received, whether in binary, tag-encoding URI,  
680 pure-identity URI, element strings or GS1 identifier keys expressed using Application  
681 Identifier (AI) representation, together with additional serialization, where required.  
682 Furthermore, the coding scheme should also be detected. The tag-length SHALL either  
683 be determined from the input value (i.e. given a binary string or tag-encoding URI), – or  
684 otherwise, where the input value does not indicate a particular tag-length (e.g. pure-  
685 identity URI, element strings or GS1 identifier keys expressed using Application  
686 Identifier (AI) representation, together with additional serialization, where required), the  
687 intended tag-length of the output SHALL be specified additionally via the supplied  
688 parameters when the input value is either a pure-identity URI, an element string or GS1  
689 identifier key expressed using Application Identifier (AI) representation, together with  
690 additional serialization, where required, none of which specify the tag-length themselves.  
691 It is important that this initial matching can be done quickly without having to try  
692 matching against all possible patterns for all possible schemes, tag lengths and lengths of  
693 the GS1 Company Prefix.

694 For this reason the Tag Data Translation markup files specify a prefix-match for each  
695 level of each scheme, which SHALL match from the beginning of the input value. If the  
696 prefix-match matches, then the translation software can iterate in further detail through  
697 the full regular expression patterns for each of the options to extract parameter values –  
698 otherwise it should immediately skip to try the next possible prefix-match to test for a  
699 different scheme or different level of representation, without needing to try all the options  
700 nested within each of these, since all of the nested regular expression patterns share the  
701 same prefix-match.

### 702 **3.5 Specification of the outbound representation**

703 The Tag Data Translation process only permits encoding or decoding between different  
704 representations of the same scheme. i.e. it is neither possible nor meaningful to translate  
705 a GTIN into an SSCC – but within any given scheme, it is possible to translate between  
706 multiple levels of representation, namely binary, tag-encoding URI, pure-identity URI,  
707 human-readable string and GS1 identifier keys expressed using Application Identifier  
708 (AI) representation, with or without parentheses. Translation to/from Text Element  
709 Identifier strings is also possible for the Aerospace & Defence Identifier (ADI).

710 With this constraint, it should be possible for Tag Data Translation software to perform a  
711 conversion so long as the input value and the outbound representation level are specified.

712 In addition, Tag Data Translation 1.6 provides for each EPC scheme an output format  
713 which is the hostname for which a type 35 ('NAPTR') DNS lookup should be made in  
714 order to effect an ONS query. Note that this is an output-only representation, as indicated  
715 in Table 2.

716 **3.6 Specifying supplied parameter values**

717 Decoding from the binary level through the tag-encoding URI, pure-identity URI and  
718 finally to the element strings or GS1 identifier keys in AI representation only ever  
719 involves a potential loss of information. With the exception of the lookup table mapping  
720 GS1 Company Prefix Index to GS1 Company Prefix for the 64-bit tags, it is not  
721 necessary to specify supplied parameters when decoding, since the binary and tag-  
722 encoding formats already contain more information than is required for the pure-identity  
723 URI, element string or Application Identifier (AI) formats.

724 Encoding often requires additional information to be supplied independently of the  
725 inbound string. Examples of additional information include:

- 726 • Independent knowledge of the length of the GS1 Company Prefix
- 727 • Intended length of the physical tag (64-bit, 96-bit ...) to be encoded
- 728 • Fast filter values (e.g. to specify the packaging type – item/case/pallet)

729

730 It should be possible to provide these supplied parameters to Tag Data Translation  
731 software. In all the cases above, this may simply populate an internal key-value lookup  
732 table or associative array with parameter values additional to those that are automatically  
733 extracted from parsing the inbound string using the matching groups of characters within  
734 the appropriate matching regular expression pattern.

735

736 Note that two specific GS1 identifier keys, namely GTIN and GLN are extended with  
737 serial numbers for EPC use. In this situation, the serial number SHALL NOT be passed  
738 via the supplied parameters. Instead, the serial number SHALL be passed as part of the  
739 input value. For the element string representation, this is achieved by appending the  
740 GTIN or GLN with with `;serial=` followed by the serial number or serialized  
741 extension. For Application Identifier representation, this is achieved through the use of  
742 AI 21 for the Serial Number associated with the GTIN - or AI 254 for the serial extension  
743 field used in conjunction with the GLN for EPC purposes.

744 In this way, either the GTIN or GLN and the serial number CAN be obtained as the  
745 output value because the same grammar is used for both input and output. This is  
746 important because the Tag Data Translation Application Programming Interface (API)  
747 defined in Chapter 6 of this document provides no direct access to the private values of  
748 intermediate variables or fields used within the translation process. Table 3 shows  
749 examples of how the input value should be formatted for serialized identifiers. Note that  
750 SSCC, GRAI and GIAI, GDTI and GSRN are already intrinsically serialized and should  
751 therefore not be appended with `;serial=...` in the element string representation and in  
752 the Application Identifier representation, the Application Identifiers (21) or (254) should  
753 not be used in conjunction with these GS1 identifier keys.

754

Coding Scheme	Example format for input GS1 identifier keys, showing element
---------------	---

	<b>string or Application Identifier (AI) representation</b>
SGTIN	gtin=00037000302414;serial=10419703 (01)00037000302414(21)10419703
SSCC	sscc=000370003024147856 (00)000370003024147856
SGLN	gln=0003700030241;serial=1041970 (414)0003700030241(254)1041970
GRAI	grai=00037000302414274877906943 (8003)00037000302414274877906943
GIAI	giai=00370003024149267890123 (8004)00370003024149267890123
GSRN	gsrn=061414123456789012 (8018)061414123456789012
GDTI	gdti=0073796100001 (253)0073796100001
GID	generalmanager=5;objectclass=17;serial=23 [No corresponding AI representation]
USDOD	cageordodaac=AB123;serial=3789156 [No corresponding AI representation]
ADI	ADI CAG 359F2/PNO PQ7VZ4/SEQ M37GXB92 ADI CAG 3Y302/SER JK23M895 ADI CAG 3Y302/serial=#284957MH  ADI DAC 4987JK/PNO PQ7VZ4/SEQ M37GXB92 ADI DAC 294HMX/SER JK23M895 ADI DAC 4987JK/serial=#284957MH  [TEI strings prefixed with 'ADI' and space character, no corresponding AI representation]

755

756 *Table 3 Example formats for supplying existing identifier formats as the input*  
757 *value.*

758

759 *Note: Definition files in TDT 1.6 also allow for an alternative representation for EPC*  
760 *identifiers based on GSI keys for which numeric Application Identifiers are defined in the*  
761 *GSI General Specifications. This additional level is denoted in the TDT definition files*  
762 *as 'LEGACY\_AI' and accepts/returns EPC identifiers in GSI Application Identifier (AI)*  
763 *notation, such as the prefix (8003) before a GRAI, rather than the construct 'grai='. The*  
764 *human readable representation that was introduced in TDT 1.0 is still denoted*  
765 *'LEGACY' in the TDT definition files and is available for all EPC identifier schemes,*  
766 *including those which are not based on GSI keys. TDT 1.6 also introduces two new*

767 *representations, 'ELEMENT\_STRING' (which is identical to 'LEGACY\_AI' except that it*  
768 *contains no parentheses around Application Identifiers) and 'TEI' for Text Element*  
769 *Identifier representation of ADI-var.*

770

771 Note that in Tag Data Translation implementations, the values extracted from the  
772 inbound EPC representation SHALL always override the values extracted from the  
773 supplied parameters; i.e. the parameter string may specify 'filter=5' – but if the  
774 inbound EPC representation encodes a fast filter value of 3, then the value of 3 shall be  
775 used for the output since the value extracted from the input value overrides any values  
776 supplied via the supplied parameters.

777 Although many programming languages support the concept of an associative array as a  
778 data type, these are not generally portable across different languages in the way that data  
779 types such as integer and string are. For this reason, the associative array of key-value  
780 pairs for the supplied parameters SHALL be passed as a string format, using a semicolon  
781 [;] as the delimiter between multiple key=value pairs. A string in this format can be  
782 readily converted into an associative array in most modern programming languages,  
783 while remaining portable and language-unspecific.

### 784 **3.7 Validation of values for fields and fields derived via rules**

785 The `field` element and the `rule` element contain several attributes for validating and  
786 ensuring that the values for particular fields fall within valid ranges, both in terms of  
787 numeric ranges, as well as lengths of characters, allowed character ranges and the use of  
788 padding characters.

789 TDT markup files use such an explicit markup of the format and constraints of each field  
790 in order to provide for a great deal of future extensibility, particularly for encoding  
791 alphanumeric characters.

### 792 **3.8 Restricting and checking decimal ranges for values of fields**

793 In some cases, the numeric range which can be expressed using the specified number of  
794 bits exceeds the maximum decimal value permitted for that identifier in its formal  
795 specification.

796 For example, the serial number of an SSCC may be up to ten decimal digits – permitting  
797 the decimal numbers 1-9,999,999,999. This requires 34 bits to encode in binary.  
798 However, 34 bits would allow numbers in the range 0-17,179,869,183, although those  
799 between 10,000,000,000 and 17,179,869,183 are deemed not valid for use as the serial  
800 reference of an SSCC – and should result in an error if an attempt is made to encode these  
801 into an SSCC.

802 In order to prevent encoding of numbers outside the ranges permitted by the formal  
803 coding specifications, the decimal minimum and decimal maximum limits of each field  
804 are indicated via the field attributes `decimalMinimum` and `decimalMaximum`.  
805 Where these attributes are omitted, no numeric (minimum,maximum) limits are specified  
806 and checking of numeric range NEED NOT be performed by TDT implementations.

807 Otherwise, where numeric values are specified, the software should check that the value  
808 of the field lies within the inclusive range, i.e.

809 `decimalMinimum <= field <= decimalMaximum`

810 Values which fall outside of the specified range should throw an exception.

### 811 **3.9 Restricting and checking character ranges for values of** 812 **fields**

813 The `characterSet` attribute of the `field` element indicates the allowed range of  
814 characters which may be present in that field. The range is expressed using the same  
815 square-bracket notation as for character ranges within regular expressions. The asterisk  
816 symbol following the closing square bracket indicates that 0 or more characters within  
817 this range are required to match the field in its entirety. Implementations may find it  
818 useful to add a leading caret (^) and a trailing dollar symbol (\$) to ensure that the  
819 `characterSet` matches the entire field. e.g. for `[0-7]*` in the TDT markup, TDT  
820 implementations may use `^[0-7]*$` as the regular expression pattern.

821 *For example,*

822 `[01]*` *permits only characters '0' and '1'*

823 `[0-7]*` *permits only characters '0' thru '7' inclusive*

824 `[0-9]*` *permits only characters '0' thru '9' inclusive*

825 `[0-9 A-Z\-\-]*` *permits digits '0' thru '9', the SPACE character (ASCII 32) and upper-case*  
826 *letters 'A' thru 'Z' inclusive and the hyphen character.*

827

828 The `characterSet` attribute allows checking that all of the characters fall within the  
829 permitted range. For example, if a user specifies a serial number for GRAI containing  
830 characters that are not wholly numeric, although the character ranges for GRAI-96 and  
831 GRAI-64 only permit wholly numeric serial numbers, i.e. characters in the range `[0-9]`,  
832 this should result in an error. Note however that an error might not be reported in the  
833 situation where a user attempts to encode an alphanumeric GRAI serial code onto a 96-bit  
834 tag in the case where the serial code supplied fortuitously happens not to contain any  
835 alphabetic characters.

836 Furthermore, a GRAI can be encoded using two alternative two headers – one for wholly  
837 numeric serial numbers (GRAI-96), the other for alphabetic serial numbers (GRAI-170).  
838 The presence of the `compaction` attribute SHALL indicate that a particular field is to  
839 be interpreted as the binary encoding of a character string; its absence SHALL indicate  
840 that the field should be interpreted as an integer value or all-numeric integer string, with  
841 leading pad characters if the `padChar` attribute is also present and the integer has fewer  
842 digits than the `length` attribute specifies.

843 Tag Data Translation software SHOULD NOT rely upon particular values of the  
844 `characterSet` attribute as an alternative to taking notice of the `compaction`  
845 attribute; certain coding schemes, such as the US DOD's CAGE code omit certain

846 characters, such as the letter 'I' in order to reduce confusion with the digit '1', when the  
847 CAGE code is communicated in human-readable format – in this case, the  
848 characterSet attribute may look like '[0-9A-HJ-NP-Z]\*', in which case a naïve  
849 search for 'A-Z' in the characterSet attribute would fail to match, even though the  
850 binary value SHOULD BE converted to a character string because the compaction  
851 attribute was present.  
852

### 853 **3.10 Padding of fields**

#### 854 **Changes since TDT v1.0**

855 Certain fields within either the binary representation, the URI representations and also the  
856 element string and AI representations require the padding of the value to a particular  
857 number of characters, digits or bits, in order to reach a particular length for that field.

858 In TDS v1.3, additional EPC identifier schemes were introduced to support GS1  
859 identifiers that have alphanumeric serial codes. Examples of these include the SGTIN-  
860 198, SGLN-195, GRAI-170 and GIAI-202. In such schemes, TDS specifies that the  
861 alphanumeric serial codes should be encoded using 7 bits per character (7-bit compacted  
862 ASCII). In some situations, the alphanumeric serial codes are allowed to have variable  
863 length in the GS1 general specifications. This in turn means that the total number of bits  
864 required to encode the alphanumeric serial field varies, depending on its length. For the  
865 GRAI-170 and GIAI-202 in particular, TDS requires the result of such 7-bit compaction  
866 of the serial number to be appended to the right with zero bits to reach a specified total  
867 number of bits. This is in marked contrast with the practice of prepending binary padding  
868 bits to the left for binary-encoded all-numeric serial numbers, such as those in SGTIN-96.

869 In version 1.4 of TDT, we took the opportunity to make the rules for padding of fields  
870 less ambiguous, both before and after encoding to binary or before and after decoding  
871 from binary. The attributes padDir, padChar and length continue to have the same  
872 meanings as in TDT v1.0 – but we also explicitly introduced a new bitPadDir  
873 attribute at the binary level to indicate whether padding with bits is required – and if so,  
874 in which direction. This is necessary because since TDS v1.3, it became necessary to  
875 also allow for padding with bits to the right, in the case of alphanumeric fields. This was  
876 not anticipated in TDT v1.0. The bitPadDir attribute is therefore intended to avoid  
877 confusion or overloading of meaning on the role of the padDir and padChar  
878 attributes, which continue to play an important role in the padding or stripping of pad  
879 characters from the corresponding non-binary field.

880 When encoding to binary from any other level (hereafter referred to as ‘non-binary’), the  
881 field itself may be padded (prior to any conversion to binary) with characters such as ‘0’  
882 or space if the padChar and padDir attributes are present in the binary level.

883 *An example of where this occurs is the CAGE code field in USDOD-96, where the 5-*  
884 *character CAGE code is prepended with a space character to the left before these six*  
885 *characters are encoded in binary as 48 bits. (The reason for this is so that the USDOD-*

886 96 could also accommodate a 6-character DODAAC code instead of a 5-character  
887 CAGE code).

888 After converting to binary, some fields need to be padded either to the left or to the right  
889 with leading/trailing zero bits respectively, depending on the value of the new  
890 bitPadDir attribute.

891 *For example, the serial number in SGTIN-96 has bitPadDir="LEFT" to indicate that*  
892 *the binary field should be prepended to the left with zero bits when encoding. In contrast,*  
893 *the serial code of a GRAI-170 or GIAI-202 has bitPadDir="RIGHT" to indicate that*  
894 *the binary field should be appended to the right with zero bits when encoding.*

895 When decoding from the binary level to any other non-binary level, there is sometimes a  
896 need to strip the leading/trailing bits from a particular direction prior to conversion from  
897 binary to integer or character string (depending on the presence/absence and value of the  
898 compaction attribute).

899 *An example of this is the stripping of the trailing zeros from the serial field of a GRAI-*  
900 *170 or GIAI-202 upon decoding from binary, before converting to a character string.*

901 After conversion from binary, the field value may need to be padded with characters such  
902 as '0' if the padChar and padDir attributes are present in the non-binary level.

903 *An example of where this occurs is the GSI Company Prefix, which may have significant*  
904 *leading zeros. For example, the GSI Company Prefix 0037000 would require this.*

905 Alternatively, the sequence of characters decoded from the binary may contain a pad  
906 character that needs to be stripped in order to produce the corresponding field in the  
907 non-binary level.

908 *An example of where this occurs is the CAGE code field in USDOD-96, where the 48-bit*  
909 *binary encoding consists of six characters consisting of the 5-character CAGE code,*  
910 *prepended with a space character to the left, which should not appear in the URI*  
911 *representations nor as part of the 5-character CAGE code. (The reason for this is so that*  
912 *the USDOD-96 could also accommodate a 6-character DODAAC code instead of a 5-*  
913 *character CAGE code within the same field).*

914 Because TDS allows bits to be padded either to the left or to the right, depending on the  
915 field and EPC identifier scheme, TDT allows the attributes bitPadDir and  
916 bitLength to appear within the field or rule elements but only when those field  
917 or rule elements are nested within a level element that has attribute  
918 type="BINARY".

## 919 **padChar and padDir**

920 The padChar attribute SHALL consist of a single character to be used for padding.  
921 Typically this is the '0' digit (ASCII character 48 [30 hex]). Other coding schemes MAY  
922 specify the space character (ASCII character 32 [20 hex]) or a different character to use.

923 The padChar attribute indicates the non-binary character to be used for padding. If a  
924 field or rule element contains a padChar attribute, then within the same level, the

925 field SHALL be padded with repetitions of the character indicated by the `padChar`  
926 attribute, in the direction indicated by `padDir` attribute so that the padded value of the  
927 field has the length of characters as specified by the `length` attribute. This applies at  
928 the validation, parsing, rule execution and formatting stages of the translation process.

929

930 The `padDir` attribute SHALL take a string value of either 'LEFT' or 'RIGHT', indicating  
931 whether the padding characters should appear to the left or right of the unpadded value.

932 The attributes `length`, `padDir` and `padChar` MAY appear within any `field` or  
933 `rule` element of the TDT markup files. Within each `field` element, all three SHALL  
934 either be present together – or all three SHALL be absent together. Within `rule`  
935 elements, there is no requirement for the `padDir` and `padChar` attributes to be present,  
936 even if the `length` attribute is specified; functions defined in rules may return a value  
937 which does not require further padding – in this case, the `length` attribute may be  
938 specified, merely in order to verify that the result is of the correct length of characters.

939 When `padChar`, `padDir` and `length` appear as attributes within a `field` or `rule`  
940 element within the tag-encoding level element, this indicates that the corresponding  
941 field in all non-binary levels may need to be padded with the padding character  
942 `padChar` within this level of representation.

943 When `padChar` and `padDir` and `length` appear within a `field` or `rule` within the  
944 binary level element, this indicates that the field should be padded with the non-binary  
945 padding character `padChar` in the direction `padDir` only immediately prior to  
946 conversion to binary and that when decoding away from the binary level, such non-binary  
947 padding characters should be stripped if the attributes `padChar` and `padDir` are absent  
948 from the tag-encoding level.

949 *For example, for a GSI Company Prefix, all non-binary levels should have*  
950 *`padChar="0"` and `padDir="LEFT"` because the leading zeros are significant and*  
951 *should appear in the URI representations, element strings and AI representation.*

952 *In contrast, for the CAGE code in USDOD-96, `padChar=" "` and `padDir="LEFT"`*  
953 *and these attributes only appear in the binary level, because any leading space padding*  
954 *should be stripped before the CAGE code or DODAAC code is inserted in a URI*  
955 *representation.*

956 For any EPC identifier scheme, the attributes `padChar` and `padDir` should not appear  
957 within a `field` or `rule` within the binary level if they also appear within the same `field` or  
958 `rule` within the non-binary levels. If `padChar` and `padDir` are specified in a `field` or  
959 `rule` within the binary level and also in the corresponding `field` or `rule` in any non-binary  
960 level, the TDT definition file should be considered invalid. Note that some fields that  
961 appear within the binary level do not appear in all non-binary levels. For example, the  
962 filter value never appears in the pure-identity URI level. For this reason, in section  
963 3.10.1, the flowchart advises checking of the tag-encoding URI representation to see  
964 whether or not `padChar` and `padDir` are defined for each field corresponding to the fields  
965 defined within the binary level.

966

967 **bitPadDir and bitLength**

968 For field or rule elements contained within a level element that has attribute  
969 type="BINARY", the additional attributes bitPadDir and bitLength may also  
970 appear. The bitPadDir attribute may either be absent or if present, must take a string  
971 value of either 'LEFT' or 'RIGHT'

972 *For the serial number field of SGTIN-96, bitPadDir='LEFT', whereas for the serial*  
973 *code field of GRAI-170, bitPadDir='RIGHT'*

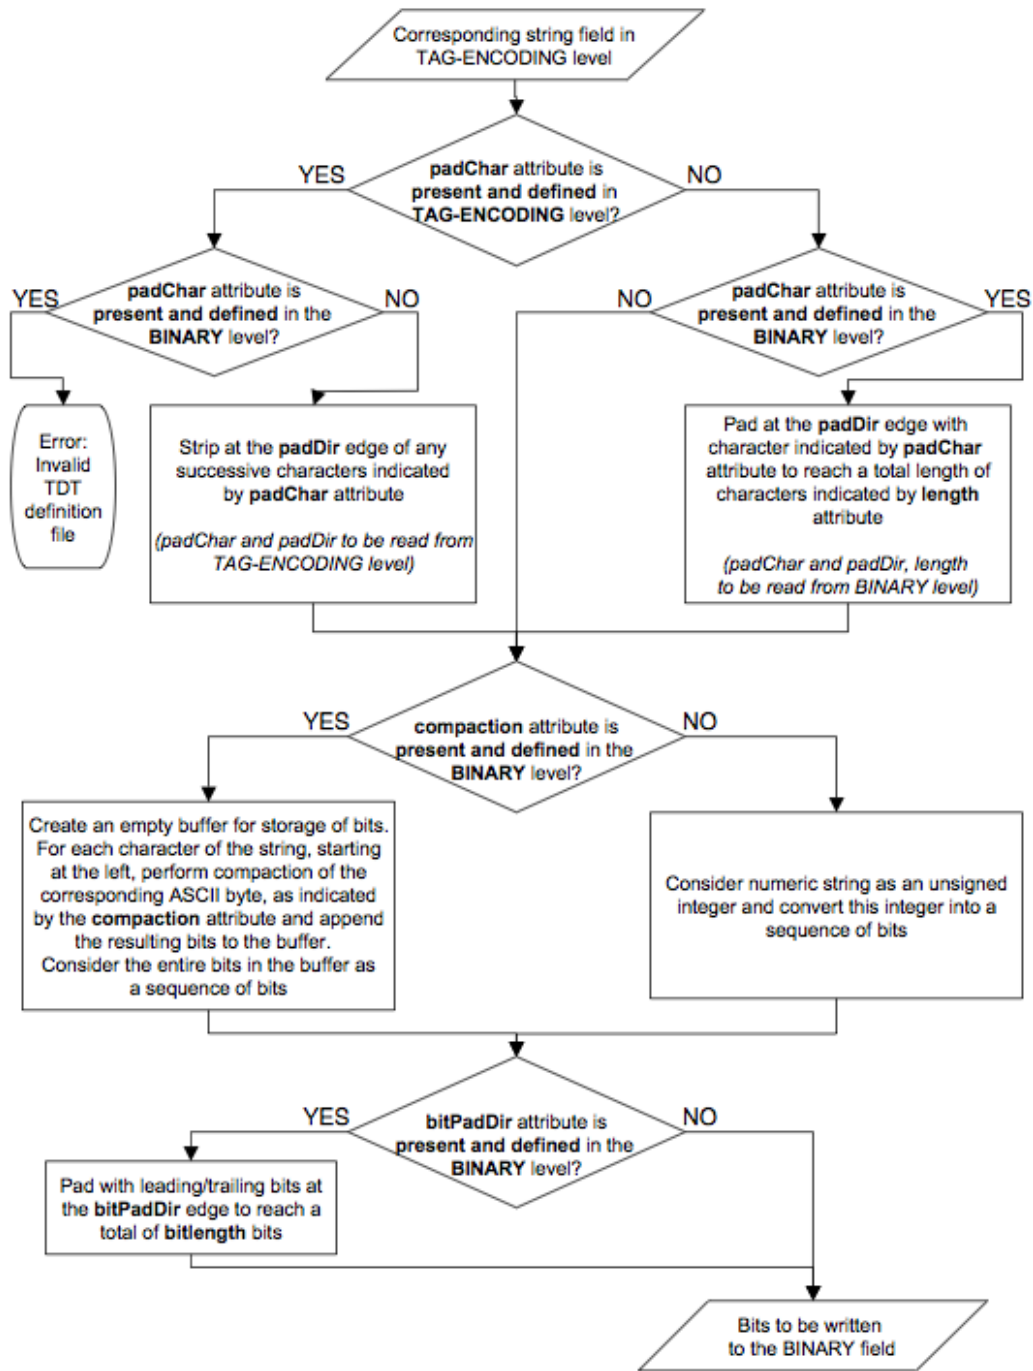

974 **3.10.1 Summary of padding rules**

975 Figure 9a is a flowchart summary of the rules about whether or not to pad a field (or strip  
976 padding characters) when encoding a non-binary field to binary encoding.

977 Figure 9b is a flowchart summary of the rules about whether or not to pad a field (or strip  
978 padding characters) when decoding a binary encoding of a field to a non-binary  
979 representation (e.g. to be used in the URI representations, element strings or AI  
980 representation).

981

982

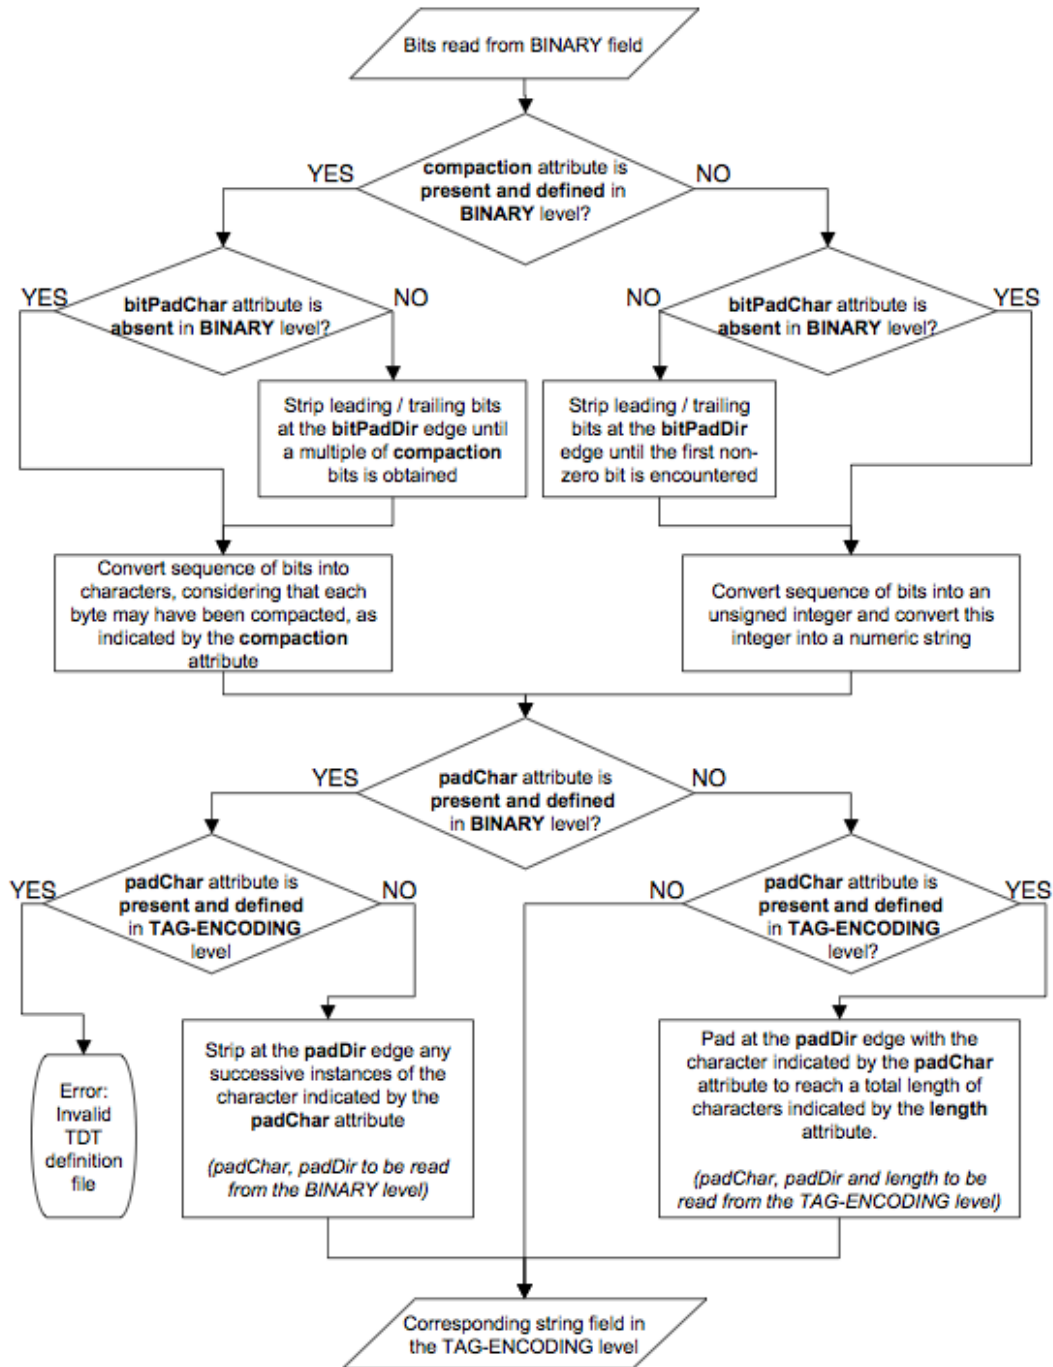

984

985

986 *Figure 9a – Summary of rules about whether or not to pad or strip a field when encoding*  
 987 *from non-binary representation to binary encoding*

988

989  
 990  
 991  
 992  
 993  
 994

Figure 9b – Summary of rules about whether or not to pad or strip a field when decoding from binary encoding to non-binary representation

995 For example, for a 96-bit SGTIN, for the field whose name="companyprefix", the  
996 non-binary levels define a length attribute of 7, a padChar of '0' and the padDir as  
997 'LEFT' for the option where optionKey = 7. For the corresponding binary level where  
998 optionKey =7, bitLength =24, bitpadChar = 'LEFT' and compaction,  
999 padDir and padChar are all absent. This means that when decoding, a 24-bit binary  
1000 value of '000000001001000010001000' read from the tag for the field named  
1001 companyprefix should be stripped off its leading zero bits at the LEFT edge, then  
1002 converted to the integer 37000, then padded to the LEFT with the pad character '0' to 7  
1003 characters, yielding '0037000' as the numeric string value for this field.

1004

1005 For a SGLN where the length of the companyprefix is 12 digits, the location reference is  
1006 a string of zero characters length. This may result in URIs which look strange because  
1007 there is an empty string between two successive delimiters, e.g. '..' in a URL which looks  
1008 like urn:epc:id:sgln:123456789012..12345

1009 This is however correct – and it is incorrect to render the zero-length field as '0' between  
1010 the period (.) delimiters because '0' is of length 1 character – not zero characters length  
1011 as required by the length attribute of the appropriate <field> element.

### 1012 **3.11 Compaction and Compression of fields**

1013 When strings other than purely numeric strings are to be encoded in the binary level of  
1014 representation, the field element contains two additional attributes, compaction and  
1015 compression. Absence of the compaction attribute SHALL indicate that the  
1016 binary value represents an integer or all-numeric string. Presence of the compaction  
1017 attribute SHALL indicate that the binary value represents a character string encoded into  
1018 binary using a per-character compaction method for economizing on the number of bits  
1019 required. Allowed values are '5-bit', '6-bit', '7-bit' and '8-bit', referring to the  
1020 compaction methods described in ISO 15962, in which the most significant 3/2/1/0 bits of  
1021 the 8-bit ASCII byte for each character are truncated.

1022 Note that a compaction value of '8-bit' SHALL be used to indicate that each  
1023 successive eight bits should be interpreted as an 8-bit ASCII character, even though there  
1024 is effectively no compaction or per-byte truncation involved, unlike the other values of  
1025 the compaction attribute. The compaction values '16-bit' and '32-bit' are not used  
1026 in the markup files for this version of the TDT specification – but are reserved in the  
1027 TDT XSD schema and SHALL indicate 16-bit and 32-bit UNICODE representation  
1028 where this is required in the future.

1029 The compression attribute is intended for future use, to indicate a compression  
1030 technique to be applied to the value as a whole, rather than on a per-character basis.  
1031 Permitted values for the compression attribute are not currently defined in this  
1032 version of the Tag Data Translation specification but those values defined in future may  
1033 indicate compression techniques such as zip / gzip compression, Huffman encoding etc.

### 3.12 Names of fields used within the TDSv1.6 schemes

The names of fields appearing in the TDT markup files are completely arbitrary but by convention SHALL consist of lower case alphanumeric words with no spaces or hyphens. There are no reserved words and the use of a name within one coding scheme does not imply any correlation with an identically named field within a different coding scheme; each coding scheme effectively has its own namespace for field names. Table 5 lists some field names that are used in the EPC schemes defined in EPC Tag Data Standard v1.6

filter	fast filter value – decimal range 0-7
serial	serial number – decimal or alphanumeric
gslcompanyprefix	GS1 company prefix
gslcompanyprefixlength	length of a GS1 company prefix as a number of characters – decimal integer e.g. for <code>gslcompany prefix = '0037000'</code> → <code>gslcompanyprefixlength=7</code>
tagLength	64/96/256 etc. – number of bits for the EPC identifier
gslcompanyprefixindex	an integer-based lookup key for accessing the real <code>gslCompany Prefix</code> – for use with 64-bit tags
itemref	Identifies the Object Type or SKU within a particular company for a GTIN
locationref	Identifies the Location within a company for a GLN
assetref	A serialised asset reference – for use with the GIAI
serialref	A serialised reference – e.g. for use with the SSCC
serviceref	Identifies the service relation within a particular company for a GSRN
documenttype	Identifies the Document Type within a company for a GDTI
cageordodaac	Either a Commercial And Government Entity or a Department of Defense Activity Address Code (used with DOD-96 scheme)
cage	A Commercial And Government Entity (CAGE) code (also including a NATO CAGE)

	(NCAGE) code) - used within the ADI-var scheme)
dodaac	A Department of Defense Activity Address Code (used within the ADI-var scheme)
originalpartnumber	The original part number (PNO) for an aircraft part (used in ADI-var in the situation where a company serializes uniquely only within the original part number)

1043

1044

*Table 5 – Names of fields used within Tag Data Standard v1.6*

### 1045 **3.13 Rules and Derived Fields**

1046 Certain fields required for formatting the outbound representation are not obtained simply  
 1047 from pattern matching of the inbound representation. A sequence of rules allows the  
 1048 additional fields to be derived from fields whose values are already known.

1049 The reason why this is necessary is that there is often some manipulation of the original  
 1050 identifier codes required in order to translate them into the pure-identity URI  
 1051 representation. Examples include string manipulation such as the relocation of the initial  
 1052 indicator digit or extension digit to the front of the item reference field – or for decoding,  
 1053 the re-calculation of the GS1 checksum – and appending this as the last digit of the GS1  
 1054 identifier key, where appropriate. Likewise, replacement of the GS1 Company Prefix  
 1055 Index integer by the corresponding GS1 Company Prefix is something that is not readily  
 1056 expressed simply via regular expressions. By working through an example for the GTIN,  
 1057 it is clear that although the processing steps are reversible between encoding into the  
 1058 pure-identity URI and decoding into the GS1 identifier key, the way in which those steps  
 1059 are defined takes on an unsymmetrical appearance in the sequence of rules. An example  
 1060 illustrates this point:

1061

1062 **Decoding the GTIN (i.e. translating from pure-identity URI into an**  
 1063 **element string or Application Identifier representation)**

1064

- 1065 • `indicatordigit = SUBSTR(itemref,0,1);`
- 1066 • `itemrefremainder = SUBSTR(itemref,1);`
- 1067 • `gtinprefix =`  
 1068 `CONCAT(indicatordigit,companyprefix,itemrefremainder);`
- 1069 • `checkdigit = GS1CHECKSUM(gtinprefix);`

1070

1071 The above are all examples of rules to be executed at the 'EXTRACT' stage, i.e.  
 1072 immediately after parsing the input value.

1073

1074 **Encoding the GTIN (i.e. translating from element string or Application**  
1075 **Identifier representation into pure-identity URI)**

1076 (assumes `gslcompanyprefixlength` is passed as a supplied parameter)

1077

- 1078 • `gtinprefixremainder=SUBSTR(gtin,1,12);`
- 1079 • `indicatordigit=SUBSTR(gtin,0,1);`
- 1080 • `itemrefremainder=SUBSTR(gtinprefixremainder,gslcompanypre`  
1081 `fixlength);`
- 1082 • `itemref=CONCAT(indicatordigit,itemrefremainder);`
- 1083 • `gslcompanyprefix=SUBSTR(gtinprefixremainder,0,gslcompany`  
1084 `refixlength);`

1085

1086 The above are all examples of rules to be executed at the 'FORMAT' stage, i.e. when  
1087 constructing the output value.

1088

1089 As the above examples show, the definitions of particular fields (e.g. `itemrefremainder`)  
1090 depends upon whether encoding or decoding is being performed (or equivalently,  
1091 whether the field is required for formatting the output value – or being extracted from the  
1092 input value), since each successive definition depends on prior execution of the  
1093 definitions preceding it, in the correct order, in order that all the required fields are  
1094 available.

1095 The rules in the example above apply generally, with minor modifications to all of the  
1096 GS1 coding schemes covered in the TDS Specification v1.6. It is worth noting that each  
1097 of the above rule steps contains only one function or operation per step, which means that  
1098 even a very simple parser can be used, without needing to deal with nesting of functions  
1099 in parentheses.

1100 **3.14 Core Functions**

1101 The core functions which SHALL be supported by Tag Data Translation software in  
1102 order to encode/decode the GS1 coding schemes are described in Table 6.

SUBSTR (string, offset)	the substring starting at <offset> (offset=0 is the first character of string)
SUBSTR (string, offset, length)	the substring starting at <offset> (offset=0 is the first character of string) and of <length> characters

CONCAT (string1, string2, string3,...)	concatenation of string parameters
LENGTH(string)	number of characters of a string
GS1CHECKSUM (string)	Computes the GS1 checksum digit given a string containing all the preceding digits
TABLELOOKUP (inval, tablename, incol, outcol)	<p>Performs a lookup in table called tablename. Given an input value &lt;inval&gt;, look in table &lt;tablename&gt; to find a match in column names &lt;incol&gt; and return the corresponding value for the same row from output column &lt;outcol&gt;.</p> <p>The TABLELOOKUP function only indicates the logical lookup – not any bindings.</p> <p>The table URL is specified via a separate attribute tableURL and bindings to XPath or SQL expressions are specified via separate attributes tableXPath and tableSQL.</p>
add(String, int)	Converts the String value to integer and adds increment to the converted value. Returns result as a String value
multiply(String, int)	Converts the String value to integer and multiplies the converted String with the integer value supplied. Returns the result as a String value
divide(String, int)	Converts the String value to integer and divides the converted String by the integer value supplied. Returns the result as a String value
subtract(String, int)	Converts the String value to integer and subtracts the supplied integer value from the converted value. Returns result as a String value
mod(String, int)	Converts the String to integer and returns the result of the remainder of the converted String after integer division by the integer value supplied. i.e. returns (String <b>mod</b> int )

1103

1104 *Table 6 - Basic built-in functions required to support encoding and decoding within the*  
1105 *GS1 schemes currently covered by the TDS specification*

1106

1107 In order to make full use of the Tag Data Translation markup files, implementations of  
1108 translation software should provide equivalent functions in the programming language in

1109 which they are written, either by the use of native functions or custom-built methods,  
 1110 functions or subroutines.

1111 In this version of Tag Data Translation, the requirement that implementations should be  
 1112 able to recalculate check digits only applies to the GS1 coding schemes, when output in  
 1113 the element string or GS1 Application Identifier representation is required. Further  
 1114 details on calculation of the GS1 checksum can be found at <http://www.gs1.org>.  
 1115 It should be noted that ISO 7064 provides a standard for more general-purpose  
 1116 calculation of check digits and that this may be considered in future versions of this  
 1117 specification.

1118 It is important to note that modern programming languages (including Java, C++, C#,  
 1119 Visual Basic, Perl, Python) do not all share the same convention in the definitions of their  
 1120 native functions, especially for string functions. In some languages the first character of  
 1121 the string has an index 0, whereas in others, the first character has an index 1.  
 1122 Furthermore, many of the languages provide a substring function which takes two  
 1123 additional parameters as well as the string itself. Usually, the first of these is the start  
 1124 index, indicating the starting position where the substring should be extracted. However,  
 1125 some languages (e.g. Java, Python) define the last parameter as the end index, whereas  
 1126 others (C++, VB.Net, Perl) define it as the length of the substring, i.e. number of  
 1127 characters to be extracted. Table 7 indicates a number of language-specific equivalents  
 1128 for the three-parameter SUBSTR function in Table 6.

1129

	SUBSTR(string, offset, length)	Notes
C++	String.substr(offset, length);	
C#	String.Substring(offset, length);	
Perl	substr(\$stringvariable, offset, length);	
Visual Basic	String.Substring(offset, length)	
Java	Java.lang.String String.substring(beginIndex, endIndex)	beginIndex = offset endIndex = offset+length
Python	String[start:end]	start = offset end = offset+length

1130

1131 *Table 7 – Comparison of how substring functions are defined in a number of modern*  
 1132 *programming languages. The parameters offset and length are of integer type.*

1133

1134 Note that for the case of rules which use the TABLELOOKUP function, additional  
 1135 attributes tableURL and tableXPath or tableSQL are provided. Tables may be  
 1136 provided in XML format or as comma-separated values (CSV) or tab-separated values

1137 (TSV), even though any Tag Data Translation software MAY internally store the table  
1138 values in a different format altogether. For this reason, the binding to the original format  
1139 is handled separately via the `tableURL` and `tableParams` and either  
1140 `tableXPath` or `tableSQL` attributes, while the `TABLELOOKUP` function expresses  
1141 the logical lookup, irrespective of the format in which any table is actually supplied.

1142

1143 As an example, consider the GS1 Company Prefix Index lookup tables for use with 64-bit  
1144 tags. An XML version and a comma-separated values (CSV) version are provided at  
1145 <http://www.onsepc.com>

1146

1147 For the XML version,  
1148 `tableURL="http://www.onsepc.com/ManagerTranslation.xml"` and  
1149 `tableXPath` and `tableParams` are one of the following pairs:

1150

1151 `tableXPath="/GEPC64Table/entry[@index='$1']/@companyPrefix"`  
1152 `tableParams="companyprefixindex"`

1153 for the case where

1154 `function="TABLELOOKUP(companyprefixindex, 'GEPC64Table', comp`  
1155 `anyprefixindex, companyprefix) "`

1156 OR

1157 `tableXPath="/GEPC64Table/entry[@companyPrefix='$1']/@index"`  
1158 `tableParams="companyprefix"`

1159 for the case where

1160 `function="TABLELOOKUP(companyprefix, 'GEPC64Table', companypr`  
1161 `efix, companyprefixindex) "`

1162

1163 The first example pair is used to obtain the value of `companyprefix` given the value  
1164 of `index` (e.g. retrieve `companyprefix='0037000'` given  
1165 `companyprefixindex='1'`).

1166 The second example pair is used to obtain the value of `companyprefixindex` given  
1167 the GS1 company prefix (e.g. retrieve `gslcompanyprefixindex='1'` given  
1168 that `gslcompanyprefix='0037000'`).

1169 Note that `tableParams` may be a comma-separated string of either fieldnames (if  
1170 unquoted) or fixed literal values, if wholly numeric or single-quoted strings. The `$1`  
1171 in the `tableXPath` expressions indicates that the actual value of the field named by the  
1172 first parameter of `tableParams` string should be substituted into the `tableXPath`  
1173 expression at this point before passing the XPath expression to an XML DOM parser.

1174 For example, if the value of `companyPrefix` is '0037000', then for the second example  
1175 pair, the value of '0037000' would be substituted in place of '\$1' in `tableXPath` so that  
1176 it would be the following XPath expression:

```
1177     "/GEPC64Table/entry[@companyPrefix='0037000']/@index"
```

1178 which is actually passed to the XML DOM parser.

1179

1180 Where more than one parameter is listed in `tableParams`, \$2 indicates where to  
1181 substitute the second parameter, while \$3 indicates where to substitute the third  
1182 parameter, and so on.

1183

1184 A table supplied as comma-separated values (CSV) or tab-separated values (TSV), can be  
1185 readily converted to a relational database table with the appropriate column headings.

1186 For the example of the GS1 Company Prefix Index table for 64-bit tags, the CSV version  
1187 is available from `http://www.onsepc.com/ManagerTranslation.csv`

1188 In this case, the attribute

1189

```
1190 tableURI= "http://www.onsepc.com/ManagerTranslation.csv"
```

1191

1192 and the attributes `tableSQL` and `tableParams` may be one of the following pairs:

1193

```
1194 tableSQL="SELECT companyPrefix from GEPC64Table WHERE  
1195 index='$1' "
```

```
1196 tableParams="companyprefixindex"
```

1197 for the case where

```
1198 function="TABLELOOKUP(companyprefixindex, 'GEPC64Table', comp  
1199 anyprefixindex, companyprefix) "
```

1200 OR

```
1201 tableSQL="SELECT index from GEPC64Table WHERE  
1202 companyPrefix='$1' "
```

```
1203 tableParams="companyprefix"
```

1204 for the case where

```
1205 function="TABLELOOKUP(companyprefix, 'GEPC64Table', companypr  
1206 efix, companyprefixindex) "
```

1207

1208 Each of the two example pairs above corresponds to the respective pairs in the previous  
1209 examples for the `tableXPath` attributes. Likewise, the notation \$1, \$2, etc.  
1210 indicates where values of fields named by parameters from the `tableParams` string

1211 should be substituted into the tableSQL expression before passing to the relational  
1212 database engine for execution.

1213

1214

1215

## 1216 **4 TDT Markup - Elements and Attributes**

### 1217 **4.1 Root Element**

1218 The epcTagDataTranslation element is the root element of the TDT definition.

#### 1219 **Attributes**

Name	Description	Example Values
version	TDT Definition version number	1.6
date	Creation Date	2011-01-18T11:33Z
epcTDSVersion	TDS Specification version	1.6

#### 1220 **Elements**

Name	Description
scheme	Please see scheme definition below for more details

### 1221 **4.2 Scheme Element**

1222 For every identifier / coding scheme as defined in the TDS specification, the Scheme  
1223 element provides details of encoding/decoding rules and formats for use by Tag Data  
1224 Translation software. In this version of the TDT specification, markup files are provided  
1225 for the following identifiers: GDTI-96, GDTI-113, GIAI-64, GIAI-96, GIAI-202, GID-  
1226 96, GRAI-64, GRAI-96, GRAI-170, GSRN-96, SGLN-64, SGLN-96, SGLN-195,  
1227 SGTIN-64, SGTIN-96, SGTIN-198, ADI-var, SSCC-64, SSCC-96, USDOD-64,  
1228 USDOD-96.

#### 1229 **Attributes**

Name	Description	Example Values
name	Name of the coding scheme	GDTI-96, GDTI-113, GIAI-64, GIAI-96, GIAI-202, GID-96, GRAI-64, GRAI-96, GRAI-170, GSRN-96, SGLN-64, SGLN-96,

		SGLN-195, SGTIN-64, SGTIN-96, SGTIN-198, ADI-var, SSCC-64, SSCC-96, USDOD-64, USDOD-96
optionKey	The name of a variable whose value determines which one of multiple options to select. Note that as of TDT 1.6, optionKey is no longer a required attribute within the <scheme> element, although it is still specified for fixed-length EPC constructs. Even if the optionKey value is not specified within the <scheme> element, nested <option> elements are nevertheless numbered with an optionKey attribute and translation is performed between <option> elements having the same value of optionKey attribute present within the <option> element.	companyprefixlength
tagLength	This refers to the length of the EPC identifier itself (e.g. the bits encoded from position 20h in the EPC/UII memory bank of a Gen2 tag). The tagLength attribute shall not be specified for a variable-length EPC identifier, although it shall be specified for all fixed-length EPC identifiers.	64, 96 or larger values. (The tagLength attribute shall not be specified for a variable-length EPC identifier)

1230

## Elements

Name	Description
------	-------------

level	Contains option elements expressing a pattern, grammar and encoding/decoding rules for each level of representation
-------	---

1231 **4.3 Level Element**

1232 This element provides a prefix match for each level of representation. Nested within the  
 1233 level element are option elements (which provide the pattern regular expressions  
 1234 for parsing the input into fields and ABNF grammar for formatting the output) and  
 1235 rule elements used for obtaining additional fields from functional operations on known  
 1236 fields.

1237 **Attributes**

Name	Description	Example Values
type	Indicates level of representation	BINARY TAG_ENCODING PURE_IDENTITY LEGACY LEGACY_AI ONS_HOSTNAME
prefixMatch	Prefix value required for each encoding/decoding level	00001010 uri:epc:tag:sscc-64 uri:epc:id:sscc sscc= (00)
requiredParsingParameters	Comma-delimited string listing names of fields whose values SHALL be specified in the list of suppliedParameters in order to parse the fields of an input value at this level	gs1companyprefixlength
requiredFormattingParameters	Comma-delimited string listing names of fields whose values SHALL be specified in the list of suppliedParameters in order to format the outbound value at this	filter,tagLength

	level	
--	-------	--

1238 **Elements**

Name	Description
option	Contains patterns and grammar
rule	Contains rules required for determining values of additional variables required

1239

1240 **4.4 Option Element**

1241 **Attributes**

Name	Description	Example Values
optionKey	A fixed value which the optionKey attribute of the <scheme> element SHALL match if this option is to be considered, provided that the optionKey attribute is specified within the <scheme> element. For variable-length EPCs, the optionKey attribute might not be specified within the <scheme> element but is still used for ensuring that the <option> element for the outbound representation is appropriate for the <option> element for the inbound representation. For all EPCs, translation shall always be between two <option> elements having the same value of their optionKey attribute	Any string value but for GS1 identifier keys, the values '6','7','8','9','10','11','12'.  In the case of ADI-var, the optionKey is used to distinguish between six recognized variations in the way in which the unique identifier may be constructed. In this situation, the optionKey is simply a number to represent a particular variation but has no specific correspondence to a particular field.
pattern	A regular expression pattern to be used for parsing the input string and extracting the values for variable fields	00101111([01]{4})00100000([01]{40})([01]{36})
grammar	An ABNF grammar indicating how the output can be reassembled from a combination	'00101111' filter cageordodaac serial

	of literal values and substituted variables (fields)	<i>N.B. single quoted string indicate fixed literal strings, unquoted strings indicate substitution of the correspondingly named field values</i>
--	--	---

1242 **Elements**

Name	Description
field	Provides information about each of the variables, e.g. (min, max) values, allowed character set, length, padding etc.

1243 **4.5 Field Element**

1244 **4.6 Attributes**

Name	Description	Example Values
seq	The sequence number for a particular sub-pattern matched from a regular expression – e.g. 1 denotes the first sub-pattern extracted	1, 2, 3...
name	The name of the variable (or field) – just a reference used to ensure that each field may be used to construct the output format	filter, companyprefix, itemref, serial, ...
decimalMinimum	Decimal minimum value allowed for this field	0
decimalMaximum	Decimal maximum value allowed for this field	9999999
length	Required length of this field in string characters.	7
bitLength	Required length of this field in bits. Omitted for all levels except for the BINARY encoding level	24
bitPadDir	Direction to insert '0' to the binary value	'LEFT', 'RIGHT'
characterSet	Allowed character set for this field, expressed in	[0-9]*,[01]*, [0-9A-HJ-NP-Z]*

	regular expression character range notation	
padChar	Character to be used to pad to required value of fieldlength. Omitted if no padding is required for the corresponding field outside of the BINARY level (e.g. within the TAG-ENCODING level)	'0', ' ' (ASCII space character)
padDir	Direction to insert pad characters.	'LEFT', 'RIGHT'

1245

1246

## 1247 4.7 Rule Element

### 1248 Attributes

Name	Description	Example Values
type	Indicates at which stage of the process the definition should be evaluated	'EXTRACT', 'FORMAT'
inputFormat	Indicates whether the input parameter to the definition is in binary format or non-binary ('string') format	'STRING', 'BINARY'
seq	A sequence number to indicate the running order for definitions sharing the same mode value. The definitions should be run in order of ascending 'seq' value	1,2,3,4,5...
newFieldName	A name for the new field or variable whose value is determined by evaluating the definition	Any string consisting of alphanumeric characters and underscore
function	An expression indicating how the new field can be determined from a function of already-known fields	e.g. SUBSTR(itemref,0,1)

decimalMinimum	For numeric fields, the decimal minimum value allowed for this field	e.g. 0
decimalMaximum	For numeric fields, the decimal maximum value allowed for this field	e.g. 9999999
length	Required length of this field in string characters.	7
padChar	Character to be used to pad to required value of fieldlength. Omitted if no padding is required. Present if padding is required.	'0', ''
padDir	Direction to insert pad characters	'LEFT', 'RIGHT'
bitLength	Required length of this field in bits. Omitted for all levels except for the BINARY encoding level	e.g. 24
bitPadDir	Direction to insert '0' to the binary value	'LEFT', 'RIGHT'
characterSet	Allowed character set for this field, expressed in regular expression character range notation	[0-9],[01]
tableURL	A URL where the data table can be obtained	http://www.onsepc.com/ManagerTranslation.xml
tableXPath	An XPath expression for obtaining a particular attribute or element value from an XML table.  The inline notation '\$1', '\$2' etc. indicates where the values of the first, second, etc. elements of the tableParams list should be substituted before passing to an XML parsing engine.	/GEPC64Table/entry[ @index='\$1']/ @companyPrefix
tableSQL	A SQL expression for obtaining a particular field from a relational database	SELECT companyPrefix FROM GEPC64Table WHERE index='\$1'

	<p>table.</p> <p>The inline notation '\$1', '\$2' etc. indicates where the values of the first, second, etc. elements of the tableParams list should be substituted before passing to a relational database query engine.</p>	
tableParams	<p>A comma-delimited string list of fieldnames whose actual values should be substituted into the tableXPath or tableSQL expressions</p>	e.g. companyprefixindex

1249

1250

## 1251 5 Translation Process

1252

1253 The execution of the rules in the TDT process takes place at two distinct processing  
1254 stages, denoted 'FORMAT' and 'EXTRACT', as explained in Table 8:

Stage	Description
EXTRACT	Operates on fields after parsing of the inbound value
FORMAT	Operates on fields in order to prepare additional fields required by the grammar for formatting the output value.

1255

1256 *Table 8 – The two stages for processing rules in Tag Data Translation*

1257

1258 The rules for each scheme are within the context of a particular level of representation.  
1259 The first block of rules, 'EXTRACT' are tied to the inbound representation level. The  
1260 last block of rules, 'FORMAT' is tied to the outbound representation level. Each block  
1261 may consist of zero or more rule elements. The rules within each block are executed in  
1262 a strict order, as specified by an ascending integer-based sequence number, indicated by  
1263 the attribute 'seq' of the rule element.

1264 The translation process is described by the following steps:

1265

### 1266 1. Setup

1267 Read the input value and the supplied extra parameters.  
1268 Populate an associative array of key-value pairs with the supplied extra parameters.  
1269 During the translation process, this associative array will be populated with additional  
1270 values of extracted fields or fields obtained through the application of rules of type  
1271 'EXTRACT' or 'FORMAT'  
1272 Note the desired outbound level.  
1273  
1274 **2. Determine the coding scheme and inbound representation level.**  
1275 To find the scheme and level that matches the input value, consider all schemes and the  
1276 `prefixMatch` attribute of each `level` element within each scheme.  
1277 If the `prefixMatch` string matches the input value at the beginning, the scheme and  
1278 level should be considered as a candidate for the inbound representation. If the scheme  
1279 element specifies a `tagLength` attribute, then if the value of this attribute does not  
1280 match the value of the `tagLength` key in the associative array, then this scheme and  
1281 level should no longer be considered as a candidate for the inbound representation.  
1282  
1283 **3. Determine the option that matches the input value**  
1284 To find the option that matches the input value, consider any `scheme+level` candidates  
1285 from the previous step. For each of these schemes, if the `optionKey` attribute is  
1286 specified within the scheme element in terms of the name of a supplied parameter (e.g.  
1287 `gslcompanyprefixlength`), check the associative array of supplied parameters to  
1288 see if a corresponding value is defined and if so, select the `option` element for which  
1289 the `optionKey` attribute of the `option` element has the corresponding value.  
1290  
1291 e.g. if a candidate scheme has a `scheme` attribute  
1292 `optionKey="gslcompanyprefixlength"` and the associative array of supplied  
1293 extra parameters has a key=value pair `gslcompanyprefixlength=7`, then only the  
1294 `option` element having attribute `optionKey="7"` should be considered.  
1295  
1296 If the `optionKey` attribute is not specified within the `scheme` element or if the  
1297 corresponding value is not present in the associative array of supplied extra parameters,  
1298 then consider each `option` element within each `scheme+level` candidate and check  
1299 whether the `pattern` attribute of the `option` element matches the input value at the  
1300 start of the string.  
1301  
1302 When a match is found, this option should be considered further and the corresponding  
1303 value of the `optionKey` attribute of the `option` element should be noted for use in  
1304 step 6.

1305

1306

1307 **4. Parse the input value to extract values for each field within the option**

1308 Having found a scheme, level and option matching the input value, consider the `field`  
1309 elements nested within the `option` element.

1310

1311 Matching of the input value against the regular expression provided in the `pattern`  
1312 attribute of the `option` element should result in a number of backreference strings being  
1313 extracted. These should be considered as the values for the `field` elements, where the  
1314 `seq` attribute of the `field` element indicates the sequence in which the fields are extracted  
1315 as backreferences, from the start of the input value, e.g. the value from the first  
1316 backreference should be considered as the value of the `field` element with `seq="1"`,  
1317 the value of the second backreference is the value of the `field` element with `seq="2"`.

1318

1319 For each `field` element, if a `characterSet` attribute is specified, check that the  
1320 value of the field falls entirely within the specified character set.

1321

1322 For each `field` element, if the `compaction` attribute is null, treat the field as an  
1323 integer. If the `type` attribute of the input level was "BINARY", treat the string of 0 and  
1324 1 characters matched by the regular expression backreference as a binary string and  
1325 convert it to a decimal integer.

1326

1327 If the `decimalMinimum` attribute is specified, check that the value is not less than the  
1328 decimal minimum value specified.

1329

1330 If the `decimalMaximum` attribute is specified, check that the value is not greater than  
1331 the decimal maximum value specified.

1332

1333 If the inbound representation was binary, perform any necessary stripping, conversion of  
1334 binary to integer or string, padding, referring to the procedure described in the flowchart  
1335 Figure 9b.

1336

1337 **5. Perform any rules of type EXTRACT within the inbound option in order to**  
1338 **calculate additional derived fields**

1339 Now run the rules that have attribute `type="EXTRACT"` in sequence, to determine any  
1340 additional derived fields that must be calculated after parsing of the input value.

1341

1342 Store the resulting key-value pairs in the associative array after checking that the value  
1343 falls entirely within the permitted `characterSet` (if specified) or within the permitted  
1344 numeric range (if `decimalMinimum` or `decimalMaximum` are specified) and  
1345 performing any necessary padding or stripping of characters.

1346

#### 1347 **6. Find the corresponding option in the outbound representation**

1348 To find the corresponding option in the outbound representation within the same scheme,  
1349 select the `level` element having the desired outbound representation and within that,  
1350 select the `option` element that has the same value of the `optionKey` attribute that was  
1351 noted at the end of step 3

1352

#### 1353 **7. Perform any rules of type FORMAT within the outbound representation in order** 1354 **to calculate additional derived fields**

1355 Run any rules with attribute `type="FORMAT"` in sequence, to determine any additional  
1356 derived fields that must be calculated in order to prepare the output format.

1357

1358 Store the resulting key-value pairs in the associative array after checking that the value  
1359 falls entirely within the permitted `characterSet` (if specified) or within the permitted  
1360 numeric range (if `decimalMinimum` or `decimalMaximum` are specified) and  
1361 performing any necessary padding or stripping of characters.

1362

#### 1363 **8. Use the grammar string and substitutions from the associative array to build the** 1364 **output value**

1365 Consider the `grammar` string for that `option` as a sequence of fixed literal strings (the  
1366 characters between the single quotes) interspersed with a number of variable elements,  
1367 whose key names are indicated by alphanumeric strings without any enclosing single  
1368 quotation marks.

1369

1370 Perform lookups of each key name in the associative array to substitute the value of each  
1371 variable element, substituting the corresponding value in place of the key name.

1372

1373 Note that if the outbound representation is binary, it is necessary to convert values from  
1374 decimal integer or string to binary, performing any necessary stripping or padding,  
1375 following the method described in the flowchart Figure 9a.

1376

1377 Concatenate the fixed literal strings and values of variable together in the sequence  
1378 indicated by the `grammar` string and consider this as the output value.

1379

1380

## 1381 **5.1 Tag Data Translation Software - Reference Implementation**

1382 A reference implementation may be a package / object class or subroutine, which may be  
1383 used at any part of the EPC Network technology stack and integrated with existing  
1384 software. Additionally, for educational and testing purposes, it will be useful to make a  
1385 Tag Data Translation capability available as a standalone service, with interaction either  
1386 via a web page form for a human operator or via a web service interface for automated  
1387 use, enabling efficient batch conversions.

## 1388 **6 Application Programming Interface**

1389 There are essentially two interfaces to consider for Tag Data Translation software,  
1390 namely a client-side interface, which provides conversion methods for users and a  
1391 maintenance interface, which ensures that the translation software is kept up-to-date with  
1392 the latest encoding/decoding definitions data.

### 1393 **6.1 Client API**

```
1394 public String translate(String epcIdentifier, String  
1395 parameterList, String outputFormat)
```

1396 Translates `epcIdentifier` from one representation into another within the same  
1397 coding scheme.

1398 Parameters:

1399 `epcIdentifier` – The `epcIdentifier` to be converted. This should be expressed as  
1400 a string, in accordance with one of the grammars or patterns in the  
1401 TDT markup files, i.e. a binary string consisting of characters '0'  
1402 and '1', a URI (either tag-encoding or pure-identity formats), or a  
1403 serialized identifier expressed as in Table 3.

1404 `parameterList` – This is a parameter string containing key value pairs, using the  
1405 semicolon [';'] as delimiter between key=value pairs. For  
1406 example, to convert a GTIN code the parameter string would  
1407 look like the following:

```
1408 filter=3;companyprefixlength=7;tagLength=96
```

1409 `outputFormat` – The output format into which the `epcIdentifier` SHALL be  
1410 converted. The following are the formats supported:

- 1411 1. BINARY
- 1412 2. LEGACY
- 1413 3. LEGACY\_AI
- 1414 4. TAG\_ENCODING
- 1415 5. PURE\_IDENTITY

1416 6. ONS\_HOSTNAME

1417

1418 Returns:

1419 The converted value into one of the above formats as String.

1420

1421 Throws:

1422 **TDTTranslationException** – Throws exceptions due to the following  
1423 reason:

- 1424 1. **TDTFileNotFound** – Reports if the engine could not locate the configured  
1425 definition file to compile.
- 1426 2. **TDTFieldBelowMinimum** – Reports a (numeric) Field that fell below  
1427 the `decimalMinimum` value allowed by the TDT markup
- 1428 3. **TDTFieldAboveMaximum** – Reports a (numeric) Field that exceeded the  
1429 `decimalMaximum` value allowed by the TDT markup
- 1430 4. **TDTFieldOutsideCharacterSet** – Reports a Field containing  
1431 characters outside the `characterSet` range allowed by the TDT markup
- 1432 5. **TDTUndefinedField** – Reports a Field required for the output or an  
1433 intermediate rule, whose value is undefined
- 1434 6. **TDTSchemeNotFound** – Reported if no matching Scheme can be found  
1435 via `prefixMatch`
- 1436 7. **TDTLevelNotFound** – Reported if no matching Level can be found via  
1437 `prefixMatch`
- 1438 8. **TDTOptionNotFound** – Reported if no matching Option can be found  
1439 via the `optionKey` or via matching the `pattern`
- 1440 9. **TDTLookupFailed** – Reported if lookup in an external table failed to  
1441 provide a value – reports table URI and path expression.
- 1442 10. **TDTNumericOverflow** – Reported when a numeric overflow occurs  
1443 when handling numeric values such as `serial number`.

1444

## 1445 **6.2 Maintenance API**

1446 `public void refreshTranslations()`

1447 Checks each subscription for any update, reloading new rules where necessary and forces  
1448 the software to reload or recompile its internal representation of the encoding/decoding  
1449 rules based on the current remaining subscriptions.

1450  
1451  
1452  
1453  
1454  
1455  
1456

1457 **7 TDT Schema and Markup Definition**

1458

1459 See <http://www.gs1.org/gsm/kc/epcglobal/tdt> for the latest version of  
1460 the TDT schema and TDT definition files for each EPC scheme.

1461

1462 **8 Glossary (non-normative)**

1463 This section provides a non-normative summary of terms used within this specification.  
 1464 For normative definitions of these terms, please consult the relevant sections of the  
 1465 document.

<b>Term</b>	<b>Meaning</b>
[Numbering/Coding] Scheme	A well-defined method of assigning an identification code to an object / shipment / location / transaction
Serialised	Provides a unique serial number for each unique object referenced using that coding scheme
GTIN	Global Trade Item Number – used to identify traded objects and services.
SSCC	Serial Shipping Container Code – provides a globally unique reference number for each shipment
GLN	Global Location Number – used to identify physical locations but also legal and organizational entities and departments
GRAI	Global Returnable Asset Identifier – used to identify returnable assets such as pallets and crates, gas cylinders, etc.
GIAI	Global Individual Asset Identifier – used to identify assets owned by an organisation, which are not being traded – often used for tracking inventory of high value equipment
GSRN	The Global Service Relation Number (GSRN) may be used to identify the recipient of services in the context of a service relationship.
GDTI	The Global Document Type Identifier is the Identification Key for a document type combined with an optional serial number
GID	General Identifier – original hierarchical structure proposed for EPC by Auto-ID Centre. GID is a generic scheme, not specifically aligned with any particular GS1 identifier key or other existing identifier scheme.
GS1 identifier keys	Fundamental identifiers used for distinct purposes and defined in the GS1 General Specifications. Examples include GTIN, SSCC, GLN, GRAI, GIAI, GDTI, GSRN. Tag Data Standard 1.6 defines EPC representations of these.

<b>Term</b>	<b>Meaning</b>
Levels of Representation	The way in which the identifier is represented. Examples of different types of representation include sequences of binary digits (bits), sequences of numeric or alphanumeric characters, as well as Uniform Resource Identifiers (URIs)
Input Value	The identifier to be translated. The format in which it is expressed is the Inbound Representation.
Inbound representation	The way in which the identifier is supplied to the translation software. This may be auto-detected from the input value.
Outbound representation	The way in which the output from the translation software should be expressed. This must be specified by the client.
Binary	A sequence of binary digits or bits, consisting of only the digits '0' or '1'
Non-Binary Form	An integer, numeric or alphanumeric character string when not expressed in the corresponding binary format
URI / URN	A Uniform Resource Identifier / Uniform Resource Name – a string that uniquely identifies any particular object. Unlike a URL (Uniform Resource Locator) which may change when a web page moves from one website to another, the URI is intended to be a permanent reference, fixed for all time – even if the underlying binding to a particular website address changes. The URI is therefore at a higher level of abstraction than a URL. Currently most web browser technology will only resolve URLs – but not URIs.
Tag-Encoding URI	A URI format which encodes the physical tag length and fast-filter values in addition to the information encoded in the pure-identity URI. Intended for low-level applications – e.g. sorting machines, tag writers, etc.

Term	Meaning
Pure-Identity URI	<p>A more abstract URI format that provides each object with a unique identity but conveys no information regarding the physical limitations of the tag used to deliver that EPC.</p> <p><i>If an object is tagged with either a 64-bit tag or a 96-bit tag, then although the binary representation and tag-encoding URIs will differ, the pure-identity URI will be the same. Intended for use by high-level applications which are not concerned with writing to tags nor sorting on packaging level.</i></p>
Physical Level[s]	<p>Representations where the encoding conveys information about the physical tag length (number of bits) and/or the packaging/classification level of the object. Specifically, the binary representation and tag-encoding URI.</p>
Identity Level[s]	<p>Higher-level representations that say nothing about the physical tag length, nor include explicit information about the packaging/classification level. Specifically the pure-identity URI, element string and Application Identifier (AI) representation</p>
Supplied parameters	<p>Parameters that shall be supplied in addition to the input value, mainly because the input value itself lacks specific information required for constructing the output.</p>
Options	<p>Variations to handle variable-length data partitions, such as those resulting from the variable-length GS1 Company Prefix in the GS1 family of coding schemes. Where multiple options are specified, the same number of options should be specified for each level of representation and translation should always translate from the matching option within the inbound level to the corresponding option within the outbound level.</p>
Regular Expression Pattern	<p>A notation for representing sub-patterns of particular groups of characters to match</p>

Term	Meaning
ABNF Grammar	<p>Augmented Backus-Naur Form. Defined in RFC 2234. [ <a href="http://www.ietf.org/rfc/rfc2234.txt">http://www.ietf.org/rfc/rfc2234.txt</a> ]</p> <p>Notation indicating how the result can be expressed through a concatenation of fixed literal values and values of variable fields, whose values are previously determined.</p>
[Fast] Filter	<p>A number which is used to conveniently select only EPCs of a particular packaging level or classification – e.g. a filter within a smart reader may be configured to report only the cases and pallets – but not all of the items within those cases. The fast filter value may also be used for filtering and sorting.</p>
Header	<p>A binary EPC prefix which indicates the coding scheme and usually also the tag length. Headers of 2 bits and 8 bits are defined in the EPC Tag Data Standard specification</p>
Field	<p>The variable elements of the EPC in any of its representations – each partition or field has a logical role, such as identifying the responsible company (e.g. the manufacturer of a trade item) or the object class or SKU. Tag Data Translation software uses the regular expression pattern to extract values for each field. These may be temporarily stored in variables or an associative array (key-value lookup table) until they are later required for substitution into the outbound format.</p>
Rules	<p>There are already a number of requirements to perform various string manipulations and other calculations in order to comply with the current TDS specification. Neither the regular expression patterns nor the ABNF grammar contain any embedded inline functions. Instead, additional fields are embedded and a separate list of rules are provided, in order to define how their values should be derived from fields whose values are already known. The rules also indicate the context and running order in which they should be executed, namely by specifying the scheme, level and stage of execution (Extract or Format) and the running order as an integer index, with functions executed in ascending order of the sequence number indicated by the seq attribute</p>

Term	Meaning
Prefix Match	<p>The Prefix Match is a substring which is used to determine the scheme of the inbound string. This is merely a method of optimizing the performance of translation software by limiting the number of pattern-match tests that are required, since the translation software only attempts full pattern matching and processing for the options of those schemes/levels whose Prefix Match matches at the start of the input value.</p>
OptionKey	<p>The OptionKey is used to identify the appropriate option to use where multiple variations are specified to deal with partitions of variable length. A default strategy may be to simply iterate through all the possible options and find only one where the format string matches the inbound string. However, this approach fails when multiple options match the inbound value. In this case, the translation software can use the enumerated value of the OptionKey to select the appropriate option to use. Each option entry is numbered – and each level specifies (via the name of a field) the appropriate option to choose. For example for the GS1 codes, the level element always specifies that the OptionKey="companyprefixlength" , so for a GS1 Company Prefix of '0037000', then field "companyprefixlength" would be specified as 7 via the supplied parameters and therefore Option #7 would be chosen for both the inbound and outbound levels.</p>
Encoding	<p>A conversion process towards the binary representation, i.e in the direction:</p> <p>Application Identifier (AI) representation or Element String → Pure-identity URI → Tag-encoding URI → Binary</p>
Decoding	<p>A conversion process away from the binary representation, i.e in the direction:</p> <p>Binary → Tag-encoding URI → Pure-identity URI → Application Identifier (AI) representation or Element String → ONS hostname</p>

<b>Term</b>	<b>Meaning</b>
Built-In Functions	Functions that should be supported by all implementations of the tag data translation software, irrespective of the programming language in which the software was actually written. See Table 6.
TDT XML Markup / Definition files	A well-defined machine-readable structured packet of data that represents the patterns, grammar, rules, and field constraints for each identifier coding scheme. Tag data translation software should periodically receive updated versions or patches of the XML markup tables, which it can then use to update its own internal set of rules for performing the conversions, whether this is done at run-time or compile-time. The TDT XML definition files are freely downloadable.
[EPC] [Tag Data] Translation Software	A piece of software that performs conversions between different representations of the EPC within any given coding scheme. The translation software may be a library module or object which may be accessed by / embedded within any technology component in the EPC Network technology stack. It may also be implemented as a standalone service, such as an interactive web page form or a web service for automated batch-processing of conversions.
EPC Tag Data Validation Software	Software which need not perform any translation but may nevertheless make use of the Tag Data Translation markup files in order to validate that an EPC in any of its representations conforms to a valid format.
EPC Network [Technology] Stack	<p>This consists of several architectural building blocks in order to connect physical objects with information systems. The technology stack includes:</p> <ul style="list-style-type: none"> <li>EPC – the Electronic Product Code</li> <li>Tags and Readers</li> <li>Filtering and Collection middleware</li> <li>Object Name Service (ONS)</li> <li>EPC Information Service (EPCIS).</li> </ul>

Term	Meaning
Checksum / Check Digit	<p>A number that is computed algorithmically from other digits in a numerical code in order to perform a very basic check of the integrity of the number; if the check digit supplied does not correspond to the check digit calculated from the other digits, then the number may have been corrupted. The check digit is in a way analogous to a message digest of a data packet or software package – except that message digests tend to be more robust since they consist of strings of several characters and hence many more possible permutations than a single check digit 0-9, with the result that there is a much smaller probability that a corrupted number or data packet will product the same message digest than that it will fortuitously produce a valid check digit. The algorithm for computing the check digit for GS1 coding schemes is specified at <a href="http://www.gs1.org/productssolutions/barcodes/support/check_digit_calculator.html">http://www.gs1.org/productssolutions/barcodes/support/check_digit_calculator.html</a></p> <p>ISO 7064 is a standard specifying a generic framework for check digit calculations.</p>
GS1 Company Prefix	<p>A number allocated by GS1 which uniquely specifies a unique company – often the manufacturer of a trade item</p>
GS1 Company Prefix Index	<p>An integer used to obtain the full GS1 Company Prefix via a lookup table, keyed on the smaller integer number of the GS1 Company Prefix Index. This is used with the 64-bit schemes in order to allocate a larger range of bits for the remaining data partitions. The GS1 Company Prefix Index is tabulated in XML and comma-separated value formats at <a href="http://www.onsepc.com">http://www.onsepc.com</a></p>
